### CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE IV.

*Dysmenorrhœa—Definition—Membrane thrown off during—Spasmodic—Inflammatory—Cause of pain in—Typical case of—Treatment of—Mechanical—Surgical treatment of.*

INTIMATELY connected with the subject of amenorrhœa is that of painful menstruation or dysmenorrhœa, as it is termed; a subject the pathology of which is still far from being clearly understood. Menstruation like all the other functions of the body to be perfectly normal should be painless, but in point of fact, the majority of women suffer more or less pain and discomfort before the appearance of, or during the flow, while in many the sufferings are very severe. In dysmenorrhœa as a general rule the pain commences about twenty-four hours before the discharge appears, increasing in severity as the period approaches sometimes becoming so intense that the patient cannot move about, but is compelled to lie down and even to roll in agony on the bed, occasionally too nausea and even vomiting occur. In due time the discharge appears, and then in many instances relief is obtained; sometimes however the pain lasts during the whole period, or becomes paroxysmal, and again not very unfrequently clots and sometimes shreds are expelled per vaginam, and instances are recorded in which large pieces of membrane, and even a perfect cast of the entire cavity

of the uterus have thus come away during attacks of painful menstruation. This dysmenorrhœal membrane is probably an exfoliation from the mucous membrane which lines the cavity of the uterus, and is most likely the result of chronic inflammation. Its expulsion has on some occasions given rise to the suspicion of pregnancy, a suspicion which a careful examination of the bag will speedily dissipate, as of course all trace of an ovum is wanting.

Authors differ greatly as to the nature of the causes producing painful menstruation, no theory has of late years been so prominently brought forward, or so warmly advocated as the mechanical one. Mechanical dysmenorrhœa and obstructive dysmenorrhœa are terms you will hear constantly made use of. Now while admitting that mechanical obstruction to the exit of the menstrual discharge occurs, I doubt that it is as frequently a cause of painful menstruation as is generally stated, nor can I admit the correctness of the axiom laid down by Dr. Marion Sims, "that there can be no dysmenorrhœa, properly speaking, unless there be some mechanical obstacle to the egress of the flow at some point between the os internum and the os externum, or throughout the whole cervical canal."\* Such an unqualified assertion made by a writer of such acknowledged weight is calculated to produce much mischief, by inducing surgeons to have recourse to operative interference for the relief of dysmenorrhœa, which in many cases may be wholly unnecessary. For practical purposes I think it sufficient to class cases of dysmenorrhœa under three heads—namely: 1st. Spasmodic; 2nd. Inflammatory; and 3rd. Mechanical dysmenorrhœa.

In spasmodic dysmenorrhœa, the pain as in the other forms precedes the appearance of the discharge. In the majority of cases it is met with either in delicate girls of feeble constitution, and leuco-phlegmatic temperament or again in women of full habit, especially if they lead an inactive life. I have pointed out to you from time to time numerous examples of this form of painful menstruation in sempstresses, and in poorly fed over-worked servants. In these cases the flow

\* "Uterine Surgery." P. 143.

is in general scanty and its appearance does not bring any marked relief, the pain continuing more or less during the whole of the period, it is not however always equally severe but is paroxysmal, being less so while the patient is warm, but becoming aggravated by the least exposure to cold. This form of dysmenorrhœa is by some writers described as neuralgic, its true nature however is very obscure, but its attacks can almost with certainty be cut short by the administration of sedatives and anti-spasmodics; and these are the remedies you should prescribe. I generally give a pill containing half a grain of opium, one of Indian hemp, and two of camphor at bed time, a combination which seldom fails to give at least temporary relief, or if for any reason opium is objectionable I substitute for it two grains of the extract of conium.

When the attacks have become habitual and the patient is consequently obliged to have recourse regularly to the use of medicines to obtain relief, I usually direct her to have by her ready for use a mixture containing two drachms of sulphuric ether, half a drachm of the liquor opii sedativus, three drachms of the tincture of hyoscyamus, one drachm of the hydrate of chloral, two drachms of the spirits of chloroform, and water sufficient to make a six ounce mixture of this she should take a table spoonful every two hours. She should bathe the feet at bed time, and if prevented by the pain from sleeping take a full dose of the hydrate of chloral. This treatment is however only palliative, and as the cause generally lies in some fault of the constitution or system at large, our object should be to correct that condition by treatment carried out during the interval between the menstrual periods, if you can detect symptoms of imperfect digestion their removal is sometimes followed by relief of the dysmenorrhœa, while if the patient be anæmic the exhibition of iron, or sometimes of arsenic, is of the greatest use. I am convinced however that many cases of spasmodic dysmenorrhœa are due to congestion of the lining membrane of the uterus, and that this is specially the case in women of full habit who lead indolent lives, and in whom great benefit follows, the adoption of more abstemious diet and more active habits, together with occasional use of saline purgatives.

Inflammatory or congestive dysmenorrhœa is a common affection and the sufferings due to it are often very acute, the pain however is generally relieved by the appearance of the menstrual flow, a fact capable of easy explanation, for the loss of blood relieves the congestion which has existed just as it would a similar condition existing in any other part of the body. In this form the uterus or at least its lining membrane is in a state of chronic inflammation, sometimes also there is associated with it an ulcerated condition of the cervical canal, sexual intercourse is generally painful, this being due to extreme sensibility of the cervix, a not uncommon result of chronic inflammation of that part of the womb. In the spasmodic form of dysmenorrhœa the pain is nearly always referred to the back, or to the lower portion of the abdomen. In inflammatory dysmenorrhœa on the other hand it is often more intense along the edge of the false ribs on the left side, shooting up to the shoulder, and down to the ovary of that side, pressure too over the ovary causes pain.

Now to what is all this suffering due? are we to believe, as is held by many that it is caused by retention of the menstrual discharge, and consequent distension of the uterus by fluid, a result supposed to be due to the closure of the os internum by the swelling of the mucous membrane which occurs in consequence of the venous congestion always present at the commencement of each menstrual period. That this may be a cause of painful menstruation I admit, but that it is a very frequent one I much doubt, the history of the following case is very instructive, and bears on the point under consideration. The patient a lady, æt. twenty-eight, who has borne five children, the youngest but fifteen months old, recently came under my care, her sufferings date back several years, and in the interval she has been twice confined. She suffered

pain over the uterus, shooting up under the left breast and round to the back for two or three days before the menstrual period, which always appeared regularly. She suffered great pain during the first day of the flow, then it gradually subsided and she enjoyed comparative ease for a time. Sexual intercourse has been for a long time back attended with pain. She did not complain of introduction of the finger into the vagina, but the moment it touched the cervix she cried out, stating however that the pain this caused was quite different from that experienced at the menstrual period. The sound passed with the greatest facility through the os internum, but though there was no obstruction to its passage, the moment it reached that point, she suffered the greatest agony and though she had been previously free from it, at once experienced the peculiar shooting pain from which she suffered so much during the menstrual period. Now this case throws some light on at least one variety of inflammatory dysmenorrhœa. No obstruction existed here, yet menstruation was excessively painful, and paroxysms of pain exactly similar to that from which she suffered during menstruation, were caused by the passage of the sound through the os internum. I believe that this patient was suffering from chronic endometritis, that the mucous membrane lining the lower portion of the cavity and the os internum, was specially engaged, that when the uterus become congested, as occurs at each monthly period, this inflammatory condition being necessarily aggravated, caused the acute pain from which she suffered, and that this was relieved when the flow set as other congestions are relieved by local depletion. I think further that the sufferings experienced by many women at each catamenial period are not mechanical, but are due to congestion of the portion of the lining membrane of the uterus indicted. The catamenial congestion rendering acutely sensitive a part which though in an unhealthy state was not before the seat of pain, it is quite possible, and indeed very probable that the swelling and thickening of the mucous membrane which takes place when this congestion occurs, may in numerous cases be sufficient to close the os internum, and thus actually oppose a mechanical obstruction to the exit of the menstrual discharge, but I cannot concur in the commonly held idea that it is the general cause of painful menstruation or agree with Dr. Marion Sims who says: "that if there be much pain either preceding its eruption or during the flow there will generally be a physical condition to account for it, and this will be of a nature to obstruct mechanically the egress of the fluid from the cavity of the womb, the obstruction may be the result of inflammation and attendant turgescence of the cervical mucous membrane whereby this canal becomes narrowed merely by the tumefaction of its lining coat, but by far the most frequent cause of obstruction is purely anatomical and mechanical." Now in the case I have just alluded to, the canal of the cervix was so patulous that I do not think it possible the lining membrane could swell to such an extent as to close the passage, and if the patient's sufferings was in this case due to mechanical causes, why should the passage of the sound reproduce so exactly the pain of the menstrual period? In my opinion it was caused by the os internum being in an unhealthy condition, and that therefore anything which increased the existing irritation, whether that were the passage of the sound or the congestion consequent on the approach of the menstrual period equally caused pain, in fine while admitting the mechanical theory as serving to explain a certain proportion of cases of dysmenorrhœa, I deny that it does so even in the majority of cases. The occurrence of congestion and inflammation causing dysmenorrhœa is of course well known, and in the foregoing remarks I merely desire to point out that in my opinion the pain is at, or immediately beyond the junction of the body with the cervix uteri, that the cause of the pain in many instances is endometritis, and that it is not necessarily due to any actual obstruction to the exit of

the menstrual discharge. The treatment of inflammatory dysmenorrhœa includes three indications.

1st. The removal of all causes keeping up the existing irritation. Foremost among these is the abstinence from sexual intercourse, for not only does the act itself generally cause pain and therefore must be injurious, but the occurrence of conception is to be specially avoided. Horse exercise, fatiguing walks, or even household occupations which necessitate much standing should be given up, while the occurrence of constipation is to be guarded against.

2nd. The inflammatory condition of the uterus is to be relieved by local depletion either by means of leeches applied before the menstrual period or by puncturing the cervix uteri and encouraging the bleeding; this latter treatment you have seen me carry out repeatedly with considerable benefit. It is not suitable to the case of young unmarried girls as it necessitates the use of the speculum, in them the leeches should be applied to the inside of the thighs, but in married women to the cervix uteri itself. Mild purgatives should also be from time to time administered, when by these means you have succeeded in relieving the congestion of the uterus, considerable benefit will be derived from blisters applied over the sacrum or to the abdomen a little above the pubes.

3rd. If the case be of long standing and that the symptoms though relieved do not entirely disappear, showing that a certain amount of endometritis still exists, I recommend you to cauterize the cervical canal and even in many cases the whole interior of the uterus with strong nitric acid. I shall on a future occasion explain to you the mode of carrying out this safe and indeed painless treatment. One other method of relieving these forms of painful menstruation depending on chronic inflammation of the uterus is so simple and so frequently efficacious that I must allude to it, namely, the use of glycerine. I do not think it suitable to the early stages of the affection, but it often answers admirably after you have carried out for some time more active treatment, it is specially useful if from the presence of ulceration or any other cause you have applied any strong caustic to the cervix, and as sometimes happens an unhealthy irritable sore remains. In such cases a pledget of cotton soaked in glycerine and introduced into the vagina will in twenty-four hours perfectly clean the sore, while the copious watery discharge which it produces will greatly relieve the local congestion. In chronic cases the injection of a few drops of pure glycerine into the cavity of the uterus two or three times a week as recommended by Dr. Marion Sims is very useful. I may here add that glycerine is the only fluid I ever inject into the uterus excepting in cases of hæmorrhage which threaten to terminate fatally. I have met with but little benefit from the exhibition of medicines in inflammatory dysmenorrhœa. Where ovarian excitement exists bromide of potassium in twenty grain doses three times a day sometimes does good, the bichloride of mercury in small dose and continued for a considerable time has been recommended by several writers, for myself I must say it has disappointed my expectations. Purgatives, especially the saline seem to me the only medicines capable of producing real benefit; these to do good should be exhibited just before the menstrual period.

It remains for us to consider those forms of dysmenorrhœa which depend on mechanical causes. Of these there are three varieties—namely, those in which the cervical canal is so flexed as to obstruct the escape of the menstrual discharge; secondly, those in which inflammation or congestion of the lining membrane exists to such an extent as to cause temporary closure of the canal or of the os internum, and thirdly, those in which from some congenital malformation or acquired cause the os internum or the cervical canal throughout its entire length is permanently narrow and constricted. To this last may be added those cases in which fibrous tumours are met with in connexion with and often probably causing dysmenorrhœa.

Painful or difficult menstruation is frequently met with

in women in whom the uterus is flexed, but though flexions of the uterus may and certainly do sometimes interfere with the exit of the menstrual flow, they certainly seldom do so unless the flexion be complicated by the existence of chronic inflammation, or the presence of a fibroid. In such case we should certainly endeavour to relieve the flexion and see if by replacing the fundus in its normal position, and supporting it there by a pessary, we can relieve the patient before having recourse to surgical means, which are less suitable in this than in any of the other forms of mechanical dysmenorrhœa. I have already so fully explained my views as to the chief cause of the dysmenorrhœa in cases of inflammatory swelling of the lining membrane of the uterus, that I have but to repeat that though not in my opinion of very frequent occurrence, cases are met with in which the os internum or some portion of the cervical canal becomes so narrowed in consequence of the tumefaction of the parts as to present a mechanical impediment to the discharge of the menses; in such cases if the treatment I have already recommended fail, I have no hesitation in having recourse to surgical treatment with the view of procuring relief; indeed it is obvious that an operation which divides the cervix so freely as does that introduced by Sir James Simpson must be calculated to give permanent relief to the congested organ. I only say again that the operation should not be had recourse to till other means have failed, including the dilatation of the cervix by means of sea tangle tents. I may here take the opportunity of saying once for all, that I unhesitatingly condemn the use of any of the metal instruments which have been suggested for the purpose of dilating the cervix; their use is attended with danger, as they act too rapidly and sometimes rupture the uterine fibres, several cases of severe inflammation and even of death are on record as following their use, while the sea tangle is perfectly harmless. A contracted os, looking almost like a pin hole and leading up to a narrow cervix uteri is not unfrequently seen; this condition is almost invariably associated with sterility, and very often with dysmenorrhœa also, you saw last week a very good example of this in the case of the young woman who sought relief for the latter affection. Menstruation is with her both painful and scanty, the os uteri so small as hardly to admit the point of a probe; there is no doubt the cervical canal is in this case unduly contracted. I think such cases as hers are fair subjects for operation, for no other treatment will be productive of permanent benefit, but beware of holding out hopes to your patient, that by submitting to the operation she will gain more than relief from the suffering caused by the dysmenorrhœa, the operation has been proposed and performed for the relief of sterility. As far as my experience goes it has resulted in failure, in other words it is in my opinion a legitimate proceeding, if performed with the view of curing cases of dysmenorrhœa, in which other treatment has failed, or is inapplicable, but that it is not warranted in cases of sterility, because the narrow os and contracted cervical canal are not the cause of the sterility, but merely an index of some congenital condition or defect in the uterus itself which hinders conception; what that defective condition may be we do not at present know.

But the patient I have first alluded to is averse to undergoing any operation, and I have therefore introduced a slender and short stemmed galvanic pessary. She has worn it for a fortnight and now tells you that she feels easier. You saw that I had some difficulty in introducing it mainly because the uterus is slightly ante-flexed. I had accordially to expose the os with the duck-bill speculum, then to seize and draw down the cervix with a fine hook, and while the womb was thus fixed to slip in the stem of the pessary. You must always adopt this method when difficulty occurs in the introduction of these instruments. I have known much good to result in such cases as the foregoing from this simple treatment, it is at least worth trying before advising that an operation should be performed.

Now with respect to the operation itself, we are indebted for its introduction to Sir J. Simpson, who for a time practised it very extensively, though I believe that before his death his views on this point were considerably modified, and that he did not perform it nearly so frequently as he had done at an earlier period of his career. His method of performing the operation was by passing an instrument termed a bistourie cachée through the canal of the cervix and within the os internum. It contained but one blade which when the instrument had penetrated to the requisite depth was made to protrude, the extent of the protrusion being regulated by a screw; the incision commenced at the os internum, and as the instrument was withdrawn it incised gradually, and more deeply the substance of the cervix till it divided the vaginal portion quite through, the instrument had then to be turned re-introduced, and the other side divided in like manner, this re-introduction is very objectionable, and consequently various knives have been invented with the view of obviating it. Those proposed by Dr. Savage, and Dr. Greenhalgh are both good instruments. I give the preference however to the former. It is furnished with two blades, the cutting edge of edge being directed outwards, but as the back of each blade when the instrument is closed projects beyond the cutting edge of its fellow which it thus overlaps, its introduction into the cervix can be safely effected, but it is generally necessary to dilate the cervical canal before this step can be effected; this indeed is generally necessary no matter what instrument is used, two pieces of sea-tangle will however open the canal sufficiently for the purpose; you should then, having exposed the os by means of the duck-bill speculum, proceed to introduce the knife slowly, taking care that it does not pass unnecessarily far into the uterus, the blades should then be expanded slowly and only to a very limited extent at first, for if this precaution be neglected you will divide the os internum too deeply, a proceeding which may cause alarming hæmorrhage and is nearly certain to be followed subsequently by such excessive eversion of the lips of the womb as to leave the neck patulous and gaping to an extensive degree; this condition exists in a patient at present under my care who was operated on more than ten years ago. When the blades are clear of the os internum they are to be expanded more widely, but I think it safer not to divide the vaginal portion of the cervix with them, but to complete this part of the operation subsequently by means of a pair of curved scissors. Dr. Marion Sims varies the operation by dividing first one and then the other side of the vaginal portion of cervix with a pair of bent narrow bladed scissors, he then passes a narrow bladed knife through the os internum and cuts from within outwards. The operation of dividing the cervix uteri is not devoid of danger; it has, though not in my practice, been followed by fatal results. I have known very alarming hæmorrhage to occur both at the time and also some hours subsequently, you should therefore be always prepared for this contingency and be provided with a solution of the perchloride of iron in glycerine; with this you should invariably brush over the divided surface, and should hæmorrhage occur insert a pledget of cotton saturated with it into the cervix and then plug the vagina. The operation itself seldom causes pain, and if the woman be healthy the chance of inflammation following is not great, still extreme care should be taken to guard against such occurring, and she should be kept in bed for several days. There is often a great tendency in the incisions to unite; to prevent this Dr. Coglean has suggested the insertion of a thin roll of lead, this answers the purpose very well. It is sometimes necessary to introduce and leave in the cervix an expanding spring tent, but not unfrequently these precautions may be dispensed with. Dr. Graily Hewitt recommends with the view of preventing contraction, and at the same time of keeping the canal straight, that the patient wear for some time subsequently an ebony stem pessary, a proceeding which in many cases would doubtless be useful.

## NATIONAL HEALTH.

(A Lecture delivered at the Royal College of Physicians of England.)

By DR. ACLAND, F.R.S.,

Regius Professor of Medicine in the University of Oxford.

PART III.—Continued.

I would refer to the report of the Sanitary Commission for details as to the medical officers of health, and their official coadjutors, as well for discussions concerning the area over which they should act. The good working of the *local authorities* does not depend entirely upon their constitution. Bentham evidently relied on the *central authority* for regulating and instructing the local executive. The Bill introduced by Mr. Goschen, arrived at the same result. By Part VI. and a few clauses in Part VIII. of that Bill, the central authority was to consist of a Minister, who should preside over the public health, relief of the poor, and all local government connected therewith. The subjects now distributed through various offices, would be united under the direction of this Minister. It is a misfortune that in consequence of being linked with the complex and difficult cognate question of incidence of local taxation, the clauses which would have made the strong central health office were withdrawn with the fiscal portions. They were not necessarily connected. The executive, indeed, once remodelled, would have fresh powers to adjust further detail. It would be wholly premature, if it were becoming, here to inquire into the detailed construction of the office of the Health Minister. Suffice it that, when that portion of the Bill has passed, the prevention of disease, and the promotion of national health will take equal rank with the first preservative functions of the State, and everything else connected with the office and its executive will fall into place.

The office will start with a staff connected with every spot in the country. The kind of complementary aid, and the extent of aid which the office may require, will be quickly discovered, and all that is valuable in the functions described in Bentham's crabbed system will be performed. In connection with these functions it may not be out of place to quote from the Sanitary Commission the following details.

Under the minister there would be sub-departments for—

- "a. Law of local government.
- "b. Engineering.
- "c. Registration and statistics.
- "d. Relief of poor.
- "e. Medical care of public health and poor.
- "f. Legislation bearing on the profession of medicine.

"III. A body of inspectors attached to the Health Office. These are to be of two kinds, as at present, with a third body of consulting experts.

"1st. General inspectors attached to, and generally residing in the 'registration divisions,' 'poor-law districts,' or (as they will also be) 'public health areas.'

"2nd. Special inspectors, viz., legal, engineering, scientific, and medical.

"3rd. Special experts, whose names should be attached to the Office, and who should advise professionally on special points for special fees, such persons to be appointed for five years and re-eligible.

"4th. Then will be required local clerks of unions, and of town councils, local surveyors under local boards and unions, local public health (medical) officers of local boards, unions, parishes, subordinate executive officers.

"No office now existing need be destroyed. Some will be amplified. A few more clerks will be required at the Central Office, and an arrangement made for obtaining

special advice when needed, in aid of the permanent staff of the office, and of the inspectors.

"The advantages are many. Not only will the plan be efficient and complete, but it will be economical. The work of the Local Government, Law, and Engineering departments, of the Registrar-General, of the Poor-law Board, of the medical adviser of the Privy Council, will be harmonized, and will never be chargeable either with unnecessary repetitions or with omission, as at present. So also, neither money nor skill will be wasted.

"All reports bearing on public health will be connected one with the other, mutually illustrating each other. They will cover the whole ground of the science of prevention of disease, which has become both so important and serious for the well-being of old and densely-peopled countries. The connection of the office of the Minister of Health with the medical profession, 4,000 members of which would be in direct relation to him, would in itself be beneficial to the whole country. It would disseminate established scientific knowledge uniformly through the country districts, affecting not the medical men only, but the clergy and the schools, doing in that way alone as much at least as direct legislation for the same purpose could do. It would bring to light in every corner all that could be advanced as bearing on the physical condition of the masses of the people, while all crude theories or impracticable plans would instantly fade before the experience of the Central Office.

"The publications of the statistical department would exhibit what could be shown of the progress of sickness. They might give also useful deductions from local meteorological and scientific observations, in connection with those of Kew, the Government Meteorological Office, the Meteorological Society of Scotland, and such private enterprises as those of Mr. George Symonds on rainfall. They would furnish data for sanitary maps, which can only be of any worth when carefully constructed on rigorous local knowledge, and they would in time get rid of the fallacious application of conclusions deduced from averages, and erroneously applied to particular places or instances. In this way, the real causes of variation in death-rate would be more surely ascertained than at present.

"Great encouragement should be given to the local public health officers to send in any observations which would promote the progress of accurate knowledge.

"The British Public Health Reports thus constructed, printed in an uniform 8vo. form, stitched in five parts, (legal, statistical, engineering, medical (including medico-legal), and general papers of inspectors), would be a series of great value. The Central Office should immediately on the first issue of the collected series make arrangement for regular interchange with all foreign countries of similar reports, according to the established usages of academies. These documents should be accessible for reference in the public health library of the minister, to all persons connected with the department.

"Public health laboratories should be maintained or aided by grants from time to time. In them not only points bearing on the general pathology of man and animals, would be from time to time investigated under the best guidance, but persons would be trained to be thoroughly qualified in all medico-legal questions. Hereby some of the scandal of ex-parte scientific witnesses might be checked or removed. Such laboratories should be aided or maintained as well in the metropolis as in some of the great towns where scientific institutions and medical schools exist, *e.g.*, Oxford, Cambridge, Birmingham, Leeds, Newcastle, Bristol. These centres are conveniently situated for various sections of the kingdom. From the state-aided laboratories the inspectors would obtain analyses of waters, or in disputed cases, of any substances requiring examination."

The following passage also demands special consideration :—

"In giving a judgment on the question of State organi-

sation relative to public health, much of the general tenor of modern legislation with respect to our internal economy should be present to the mind. It must therefore be remembered that those who will be responsible for local sanitary administration will have collectively, if not individually, to administer Acts bearing on the following subjects :—

- "§ 10. 1. Plans bearing on sanitary engineering or on local government, *i.e.*, drainage, sewerage, water supply, baths and washhouses, nuisances, offensive trades, smoke, public places of recreation, streets and roads, buildings, cellars, and lodgings, burial-grounds, mortuaries, appointments of officers, artisans' dwellings, labourers' dwellings.
- "2. Care of personal health and safety, *i.e.*, health in factories and workshops, mines, bakehouses, dangerous occupations.
- "3. Regulation of quality of food, *i.e.*, adulterations, markets, diseased cattle, slaughter-houses.
- "4. Medical, *i.e.*, prevention of disease, epidemics, endemics, syphilitic disease, small-pox, (vaccination), quarantine, lunacy, hospitals, whether, first, rate supported, such as workhouse hospitals, or hospitals under local boards, or secondly, voluntary, whether general or special, endowed or subscriptional county or small village hospitals, or hospitals for the insane, and prisons, sale and adulteration of drugs, poisons, supervision of reports of officers of health.
- "5. To which must be added medico-legal arbitrations."

An important step has been recently taken by Dr. Stokes, the Regius Professor of Medicine in Dublin, and his colleagues. They have instituted an examination with the view of granting a diploma in the subjects bearing on National Health, or, as it is sometimes called, State Medicine. This examination, of which full particulars are given at the end of the present Essay, will comprise certain parts of Law, Engineering, Pathology, Vital and Sanitary Statistics, Chemistry, Meteorology, and Medical Jurisprudence. That such opportunity of systematically learning what is essential to the maintenance of the national health should be now given by Trinity College, Dublin, (*a*) does great honour to that enlightened body. It is to be hoped that ere long, a learned compendium of the required knowledge will issue from the Irish press. Any one who has studied this subject knows, that in consequence of the labours of Parkes (*b*), Simon (*c*), Farr (*d*), Seaton (*e*), Glen (*f*), Rumsey (*g*), Rawlinson (*h*), Stewart (*i*), Tom Taylor (*j*), A. S. Taylor (*k*), Christison, Miss Nightingale (*l*), the London, Liverpool, and Glasgow Medical Officers of Health, and in other countries, Quetelet (*m*), Pettenkofer

(a), Michel Levy (b), Hammond (c), Bowditch (d), Derby (d), and other persons, have amassed so much valuable matters that the time is come when selection and abridgement are indispensable for the guidance of the student.

I must apologise for the length to which these simple thoughts have led me. They are uttered now because the time is certainly come when we must all endeavour, in our yearnings for the material improvement of our people, thoroughly to comprehend the fundamental and combined laws of Physiological and Social science on which our nature rests. Their complexity depends chiefly on the mutual action or re-action of matter and of mind in individuals, together with some superadded perturbation of civilised life, from which the savage is exempt (e). The laws of our material nature are as absolute as those of the unreasoning brutes. But, in some particulars, they are entirely subject to our will, which is not the case with any other creatures. It cannot be said, indeed, of the past life of the human race,

“Old age and experience, hand in hand,  
Lead it to death, and make it understand,  
After a season so painful and so long,  
That all our life we have been in the Wrong ;”

but this nevertheless is true, that historical and political experience, combined with the inter-communication of ideas by telegraph, and of persons by steam, is changing the conception, the conditions, and future of humanity, whether for good or for evil, with wholly unprecedented rapidity ; and this is so, not in one country, but surely and steadily through the whole world. It is quite certain that education, acting with political causes, will modify the structure of old countries. It is quite certain that education, if possible without due attention to the material conditions of the people, will add mental suffering to physical. The modifications in the material state of man will be happily effected, in proportion as they coincide with the laws of the universe, or run athwart them. Every attempted rebellion against their spiritual or material conditions will necessarily end in certain and deep disaster to the rebellious race. Our sanitary regulations must be based on a right comprehension of these laws ; on a conviction that material advantages, though essential for man, are not all ; that material comforts, will not remedy the results of immorality ; and that wisely devised sanitary arrangements, the attainment of which, even by compulsion, has not yet been achieved, would in all probability be spontaneously carried out by an educated, free, and God-fearing people.

## PRACTICAL OBSTETRICS—No. 2.

By FRANCIS E. CLARKE, B.A., M.B. DUB., &c.

ABOUT eleven o'clock p.m., on the 26th of January last, I was summoned to extract an afterbirth from a woman who had been confined early in the afternoon, but, notwithstanding the efforts of the midwife in attendance, the third stage of labour had failed to be completed. On arrival about an hour subsequently, I found the placenta retained most rigidly. There was no hæmorrhage but traction on the funis gave the sensation of most powerful

counter-resistance. As no result seemed likely to accrue from any further delay, I accordingly proceeded at once to introduce my hand into the uterus though slowly of necessity owing to the pelvis being small and to the presence of considerable spastic contraction about the cervix. Finding the greater portion of the fundus intimately adherent to the placenta and the womb firmly contracted throughout, I endeavoured to break down the adhesion as gently as possible, and after much patient and extremely gentle perseverance, removed it, but found on the extrusion of my hand that a portion of it had been left behind ; again I introduced my hand and detached as much of the remainder as possible, still manipulating with the greatest care, but on the re-withdrawal of my hand and the detached portion of placenta which remained, most violent hæmorrhage ensued which, with the very greatest difficulty I arrested by means of the cold water douche vigorously and copiously applied, and pressure ; the latter of which I had kept up manually for fully an hour after the cessation of hæmorrhage, when I substituted a hard pad and tight-binder firmly secured. Stimulants I administered pretty freely at the time as there was necessity, and prescribed ergot and gallic acid in mixture. On the evening of the third day symptoms of acute metritis made their appearance, and I at once ordered warm applications to the abdomen and exhibited calomel and opium (twelve grains of the former to be well rubbed up in two scruples of the pulv. cretæ co. cum opio., and a sixth part taken every two hours). Under this treatment she became slightly mercurialised, and all untoward symptoms speedily subsided, the woman subsequently making a most satisfactory recovery.

Hæmorrhage continuing subsequent to the completion of the second stage coincident with retention of the placenta is usually said to be present in cases of morbid adhesion and somewhat indicative of that causation of retention in the differential diagnosis betwixt it and hour-glass, or other irregular uterine contractions which also prevent normal expulsion of the placenta. In the case I have so briefly cited there was not a trace of hæmorrhage nor do I believe it for a moment to be unique with regard to this. I should rather imagine the presence of hæmorrhage to be variable in this as in other complications depending much on the normal contractile power of the muscular fibres and on the usual proximate and remote influences which either promote or retard uterine contraction in the parturient female after the expulsion of the fœtus. The extent and position also of the adherent portion most likely tend materially to modify the production or extent of hæmorrhage according as the action of the circular fibres be more or less impaired by the placental adhesion and consequent mechanical restraint. When the uterus contracts evenly over the adherent placenta, its cavity is so completely filled there seems no more reason why hæmorrhage should result than in the case of an irregularly contracted womb incarcerating an afterbirth, which otherwise would come away easily in which case there is very frequently none at all ; but the very fact of the presence of the placental mass in the uterus tends to prevent the secure contraction of that organ. The absence of hæmorrhage in the instance previously recited was, I apprehend, owing to the firm and regular pressure exerted over the placenta by the contracted womb, and to the large extent of surface over which the adhesion extended ; the cervix was firmly contracted which rendered the introduction of my hand tedious, and this contraction appeared to be general throughout the entire viscus without any irregularity of distribution, and I query if its production was not favoured likewise by the situation of the adhesion which seemed to me to be the fundus, and we can readily conceive by calling to mind the manner in which the uterus contracts, how irregular the contractile influence would be were an adhesion at one side, and how little on the contrary its normal contractions would be influenced by adhesion seated fairly at the fundus. Where there are two or more spots adherent with an intervening portion or portions free there must be hæmorrhage of an extensive character, contraction

being mechanically impeded and interspaces left where, through want of contraction, the gaping vessels remain patent to the extreme danger of the patient.

There is no operation in midwifery requiring greater care than the extraction of a placenta retained by morbid adhesion; for in addition to the ordinary danger of rupturing the uterus when introduction of the hand is necessary, there is extreme difficulty to be encountered in avoiding a wound of the internal coat of the womb or setting up acute endometritis when detaching the placenta, and the great expediency at the same time of persevering in order that the entire mass may be removed. Where the extent of adherent surface is so great as it was in the present case, it is extremely difficult, and I should think sometimes, impossible to remove the placenta entire. I failed to do so, and the question, not only then, but ever since, appeared to me to be doubtful, though of great practical importance whether re-introduction of the hand is advisable with a view toward the removal of the remaining portion. Such was my practice on the occasion in question, but the subsequent hæmorrhage was so great the woman was well nigh losing her life from its immediate effect, but had I not done so and extracted after detaching the retained piece of placenta, I have no doubt but putrefactive consequences would have been fatal, pyæmia, uterine phlebitis, metritis, or some kindred affection. Indeed, I am uncertain whether the metritic symptoms which supervened were owing to the result of manipulation, or to a very small shred of placenta which I believe I left even after the second manipulative interference. It may be advanced theoretically that the entire placenta should be removed at once, so that re-introduction would be unnecessary, but when the extent of adhesion is so great and the amount of contraction so powerful, it becomes simply impossible in practice; and it seemed to me preferable to risk the hæmorrhage and the danger of wounding the uterine tissue by prolonging and repeating my endeavours than to leave the patient so imminently in danger of ultimate consequences from retention of a portion of placenta most liable to putrefy, control over the former being much more in the power of the obstetrician than the cure of the latter is in that of the physician, and besides, a very small piece of retained placenta may, by preventing a permanent contraction, entail in itself a most dangerous, if not, fatal hæmorrhage. That such an undetached and unextracted portion of afterbirth may be the hystogenetic origin of a subsequent uterine polypus is easily conceivable, and has some years since been demonstrated by Dr. Stadfeldt in an essay translated by that accomplished linguist, Dr. W. D. Moore, for the *Dublin Quarterly Journal*, and were this result alone in the prospective, a complete removal of all placental debris would be so desirable as I think even to indicate the advisability of a second manual attempt in case it should be required, the operator at the same time not failing to bear in mind the danger of severe hæmorrhage occurring after the second withdrawal of his hand.

Regarding the treatment I pursued ultimately—headache, hot skin, rigors, furred tongue, nausea, in fact, the ordinary symptoms of aggravated pyrexia, with suppression of the lochia and abdominal pain and throbbing centred over the seat of the uterus were indications which I considered sufficient to urge a prompt and vigorous exhibition of calomel and opium. I first satisfied myself thoroughly as to diagnosis, felt no doubt it was metritis I had to deal with, and lost not a moment's delay in administering mercury; in the first place because even my short experience has aroused me confidently to its great value if given early enough in inflammatory affections of the uterus or its appendages; secondly, because I feared the supervention of uterine phlebitis and pyæmic absorption and believed the pre-exhibition of mercury to be the only weapon of the least utility in my possession; and thirdly, inasmuch as although I believe it to be almost specific when given early enough after the first appearance of the symptoms, yet its administration subsequently is, I fear, nearly valueless, at all events, its therapeutic value is decidedly lessened by

delay, whilst the patho-genesis of physical disease is too rapidly being developed toward a state of maturity, whose morbid effects the physician unhappily finds too frequently invincible.

Rare, though morbid adhesion, between uterus and placenta may be considered, statistics demonstrate its existence much more frequently than is generally supposed. I know of one very successful obstetrician, a man of long and large experience in England, and of well-merited reputation, who disbelieves the existence of such a condition, having removed, by manual introduction, many placentæ without once discovering a morbid adhesion. Such scepticism, ridiculous though it be, may be readily conceived, when after long experience, not a single example presented itself. The great danger, however, caused by the complication when it does arise, and the difficulty and disagreeable nature of the necessary operative interference suffice to claim for its consideration considerable importance with the thoughtful mind, and although we are aware of several pathological conditions giving rise to it, amyloid degeneration, carcinoma, inflammatory action, &c., yet I imagine there still remains much to be solved regarding it, as it seems not unlikely that the amount of hæmorrhage to be expected is, to no inconsiderable a degree, modified in each respective instance by the condition from whence the morbid adhesion originates, whilst the prognosis also would necessarily vary accordingly. In this case which was one of difficulty and danger, I am of course not in ignorance of the fact that a more skilful and experienced obstetrician might, by the assistance of such accomplished tact and acumen of which I cannot boast, possibly have removed the placenta entire in the first instance and avoided in a great measure the extreme danger of hæmorrhage which was so nearly fatal, but I think, nevertheless, that the careful attention bestowed during the operation, the precautions taken to check the hæmorrhage, and, in no small degree, the subsequent treatment, did contribute materially in producing the successful result which eventuated.

#### SURGICAL NOTES FROM THE FRANCO-PRUSSIAN WAR.

(Continued.)

By J. C. P. WIDDUP, L.R.C.S.I., L.K.Q.C.P.I.

(Irish Ambulance).

To enter minutely into the subject of gun-shot injuries of the foot, and to dwell at any length on the various stages passed over by the many such cases I have witnessed, on their progress of recovery or the reverse, would take up more time and occupy a larger space than is my present intention to devote to the subject, as I wish to make a few comments on wounds implicating other parts of the body, more deserving of notice from their singular character and peculiarity of position. I shall pass on to a class of wounds still more hopeless, and whether operated on by resection or amputation, has seldom, during this war rewarded the operator with satisfactory results. I allude to bullet wounds of the knee-joint and head of the tibia. One case of this kind in particular I shall mention, as affording an exception to the general result of such cases during the campaign.

At the battle of Artenay, which took place on the 1st, 2nd and 3rd, of last December, it is already well known how much the French army suffered from insufficiency in their medical and commissariat departments, and how that wounded men had been left lying on the field for many hours when the ground was covered with snow, and their clothing of that light description altogether inadequate to resist the intense cold. On the day previous to the bombardment of Patay, a pale emaciated looking man was brought to me suffering from a bullet wound which entered his left knee-joint by the outer edge of the patella and passing downwards and inwards, came out

through the inner tuberosity of the tibia. Synovial fluid and blood were coming through both apertures, and his suffering as might be expected from the severity of his injury, was most intense; the fact of his having remained on the field for upwards of eight hours in the depth of winter, with merely a thin piece of tent cloth to protect him from the severity of the weather, did not tend to improve his chances of recovery. In addition to this, it was necessary to convey him a distance of twenty-four miles before anything in the way of comfort could be got for him. Upon arriving at Chateaudun, where our hospitals were situated, his nervous system was so thoroughly unstrung, that any allusion to operative interference only tended to make him the more miserable, and no argument would induce him to consent. Taking all things into consideration, I thought it better to let the poor fellow remain quiet, in hopes that after a short time he would survive his hardships and allow me to operate on his knee, when his condition was somewhat better. To allay his suffering I kept him on large doses of opium, which he would call out for night and day. Two days after his entry into hospital, the inflammation around the joint extended for some distance up the thigh, but after leeching and poulticing it somewhat decreased. Subsequently suppuration set in, and the discharge came away in large quantities. Abscesses extended above the patella where, upon slight pressure, the pus would well through the bullet openings showing the communication which existed. He got five grains of quinine each day, which agreed with him so well, that to my satisfaction his general health began to improve and he could take his food with something like a relish. Still no persuasion would induce him to consent to operation, and I began to think his obstinacy would eventually be his executioner. No bad symptoms however arose, and after some time, small pieces of bone would continually come away from the openings, which seemed to ameliorate his sufferings; the abscess above the patella closed in and became less apparent, and the circumference of the parts gradually diminished. The patient himself always hopeful of his condition, appeared quite happy at the progress of events, he would sit up in his bed during the day enlivening his companions with anecdotes of his adventures and declare himself to be far better situated than his comrades in the army, who were enduring the hardships which he had endured while with them; though only three weeks had elapsed since his entry into hospital from the field, he looked forward to his recovery as a matter of certainty, and was always disconcerted when told that the joint was immovably fixed, and that in case he recovered from the injury he should be satisfied to walk without bending his knee. More than once I caught him endeavouring to flex his leg, but feeling some pain in doing so, he desisted after a few attempts. I applied mercurial ointment and plaster round the joint according to Scott's method, cut in such a manner as to leave the bullet holes exposed and give the discharge full vent; daily he improved in health and strength, and daily the tenderness on pressure became less acute, the bones became firmly ankylosed, no pain was experienced upon pressing on the instep, and I left him with every sign and symptom to warrant me in believing his recovery will be a complete one. This is of course one of those exceptional contradictory cases which can form the basis of no rule, except that it is a difficult matter to pronounce with any degree of accuracy upon the issue of cases, where frequent experience would point to a fatal termination. At the same battle of Ardenay I saw a case somewhat similar, where a Prussian officer was shot through the middle of the patella, which bone was of course broken into fragments, and the bullet having passed through the joint came out in the popliteal space, not however injuring the artery; he was amputated through the lower third of the thigh by Dr. Baxter, and was afterwards removed by the Prussians on their way to Orleans, so I know nothing of his subsequent history. It has been the uni-

versal practice in all case where the knee-joint is penetrated, either to resect it or amputate the limb, and as I before mentioned, resection became the more popular of the two during the latter period of the campaign; but under the following conditions, penetration may be so far simulated as to deceive the most practised surgeons, especially if the patient be seen a couple of days after the receipt of the injury when the synovial fluid has ceased to show itself, where from the violent concussion of a bullet passing through the adjoining structures, the most aggravated form of synovitis involves the joint where the bullet coming in contact with a hard structure, changes its course, and passing around through the soft parts, comes out at a point corresponding to where its exit might be expected, had it not been turned aside; and where, from fusion and locking of the parts as is most frequently the case, it becomes a dangerous matter to make use of the probe too freely. I merely mention this, because I have seen more than one instance, where operation was performed, and the joint in reality unimplicated. Gun-shot wounds are not seen in every day practice, and no book or verbal information will efficiently prepare men to treat what in itself may be considered a most complicated branch to the voluminous tree of the science of surgery. The subject has changed and re-changed so often, according to the experiences of so many men, or the most acceptable theory of authors—there has been no war engaged in that old ideas have not been laid aside, and new ones advocated, or *vice versa*. That a man acting on the ordinary principles of common sense, treating the symptoms as he sees them, and using a certain amount of caution in his practice, will, in the end, be more likely to have a larger percentage of successful cases, than one who bases his treatment entirely on the ideas of others, and tries to couple what he sees in reality with what he has read of in books.

Bullet wounds penetrating the pelvis, as might be expected, were mostly all fatal. I had one case, however, which recovered, and from the peculiar circumstances attending it, I may mention it as being perhaps the most curious one I encountered during the war. After the engagement at Varize, a young soldier was picked up by one of our waggons, and brought into Chateaudun. The ball entered about an inch to the left side of the os coccyx, without making any aperture of exit; urine was coming freely through the wound, and he complained of great pain. His story (which may be accepted with reserve), was that sometime after being wounded, he felt a great desire to stool, and upon straining, passed a large quantity of blood, and believes he also passed the bullet, it seems incomprehensible that the bullet should pass the rectum into the bladder (that it entered the latter, was evidenced beyond all doubt, from the urine passing through the wound), and having expended its force, fell back from the bladder into the rectum—I passed a catheter, but could find no sign of the bullet, so leaving the catheter in, and having given him a dose of opium to allay his suffering, I placed him lying on his side, and applied charpie dressing to his wound. On the following day, I found that the dressing was quite dry, and that all the urine had come through the catheter. There had been no motion from his bowels, nor was there any sign of blood or purulent matter by the rectum. On the third day, I gave him a small fluid injection, which cleared out the lower bowel, but no sign of anything sanguineous came away—urine continued to come by the catheter which was of course renewed. On the fourth day, I found he had removed the catheter during the night, and said he could pass urine without it, this, however, was an unsafe proceeding, so I again left it in his bladder, the wound appeared getting on well, and his only bad symptom was the unceasing pain in the region of his bladder, and all through his pelvis. On the seventh day, I removed the catheter, but passed it whenever he required to **make** water, he was constantly calling out for sleeping draughts. On the tenth day,

upon removing the dressings, I perceived a dark matter appearing from the wound. Catching in a forceps, I drew it away, it proved to be a portion of his coat, which had entered with the ball. After this, his sufferings were much abated, and there was no longer any necessity for giving him opium. In three weeks he was able to limp about on crutches. Owing to some slight paralysis of his lower extremities, he found a difficulty in walking, but his general health was good, and he was gaining strength each day; the wound was quite healed, and he only suffered now and then from shooting pains in the lower part of his abdomen. It is more than likely his story of having passed the bullet and a quantity of blood is untrue, and it seems equally probable that the ball having entered the bladder became encysted, and remained there, for during the latter period of his illness, he experienced no difficulty in passing urine, while the shooting pains in his abdomen may be consistent with a lesion of the kind having taken place. His health was always good, and the partial paralysis of his lower extremities—probably due to the laceration of some nervous trunk, was rapidly disappearing when I last saw him. My apprehension at first, was that lithotomy would have to be performed, but as he suffered so little inconvenience, and matters progressed so favourably, it is likely he will add one case more to the many on record, where bullets have remained for years encysted in the human body, without their locality being known, or their presence occasioning any bad consequences to the subject.

(To be continued.)

## EXCISION OF ELBOW AND KNEE-JOINTS.

BY JOHN ELLIOTT, A.M., M.B., Waterford.

In June 1869, I excised the elbow of a young woman, (Mary Costello), æt. eighteen, who for more than two years had been labouring under strumous disease of the joint which was laid open by abscess, with abscesses also extending up the humerus. Very high inflammatory action followed the operation, so that I thought it right to keep the parts irrigated for a fortnight or longer by cotton wick leading from a reservoir. Two sinuses leading down to uncovered bone followed, and did not close till twelve months had elapsed.

As the limbs now hang by the side, the humerus forms with the forearm an angle of  $123^{\circ}$  but the parts can be flexed on each other through an arc of  $31^{\circ}$ . Pronation and supination are perfect, and there is complete use of the wrist, thumb, and fingers, in fact of the whole hand. So the limb is still a very useful one and much more serviceable than an artificial substitute would be.

Margaret Power, æt. about thirty, and for some years subject to previous rheumatic attacks, began about five years since to suffer from pain in the left knee, which gradually became so severe and continuous as to give her little respite by day or by night, and finally was attended with permanent flexion and rigidity of the joint aggravated by frequent painful startings.

As she had undergone a variety of treatment both local and constitutional without relief, and her health, strength and spirits were giving way under constant suffering, I was inclined either to amputate above the knee or to excise it in the spring of 1870. Some doubt however was thrown on the diagnosis of the case, I was therefore induced to temporise and tried the actual cautery over and round the joint. This was followed by some alleviation of pain which, however, was slight and not permanent. The summer and autumn wore on with manifest deterioration of her condition, and in the ensuing month of November, it became obvious that unless relief could be procured the case would terminate fatally.

Accordingly, with the concurrence of all whom I had consulted and with the patient's willing consent, on the 15th of that month I undertook the operation of excision, having the co-operation of Dr. Burkitt, my colleague in the Workhouse Hospital, and also the kind assistance of Dr. George Mackesy and Dr. O'Neill, of this city.

When the joint had been laid open by the H incision, the synovia which escaped was observed to be not larger in quantity than usual. It was also quite transparent without the smallest purulent admixture. The cartilages on both the femur and tibia were however deeply eroded. When I had cut off the top of the tibia and the condyles of the femur, I was induced from some suspicious appearances on the section of the latter to remove another thin slice. We then found that the segments of the limb would not lie in a straightly extended position, and so in order to bring them into the desired apposition, I removed another wedge-shaped portion from the end of the femur—the thick end of the wedge looking forward—and thus obtained the required rectification. The patella seemed healthy and therefore was not meddled with, nor were the ham-string tendons divided—two omissions which I had no reason to regret. Lastly, an opening was made with a large trocar through the soft parts towards the outer side of the popliteal space, to provide a ready exit for any possible accumulation of pus, a precaution which in the sequel was happily found to be unnecessary. Little blood was lost, nor did any artery require ligature or torsion. The skin was brought together with nine or ten points of suture, and a piece of wet lint was laid over the wound and covered with waterproof cotton cloth drawn round and under the limb, which was then deposited in a box splint made expressly for the occasion, and so constructed that the sides and foot piece were separately removeable, thus permitting complete inspection and examination as well as the necessary attention to cleanliness and renewal of the dressings, without causing the slightest displacement or even disturbance of the parts. One opening was made in the back of the splint to receive the point of the heel, and another just under the site of the operation where the parts rested on a small air-pillow, to the equable support of which we probably owed our immunity from bagging or pocketing of pus. The extension necessary to steady the parts was made with a broad strip of adhesive plaister, which passed from the top of the tibia down one side of the leg, under the foot leaving a loop there, and up as far on the other side. That part which passed down the outside of the leg was kept to the front of the lateral mesial line, and that which passed up the inside was kept behind it, so as to obviate the tendency which the foot has to rotate outwards on such occasions. Over the adhesive plaister the leg was bandaged from the foot upwards with an elastic roller. This part of the apparatus required neither renewal or re-adjustment till the patient left her bed some three months afterwards. An elastic tape passed from the loop below the foot to the foot piece. Finally the space between the limb and the sides of the box splint was packed with curled hair—as recommended by Mr. Butcher—which I found very valuable from its firmness and elasticity.

As the operation was performed in the afternoon and had been rather tedious with a proportional large expenditure of chloroform, she remained under its influence in the evening and no opiate was administered. Next day apparently from the same cause, there was anorexia with vomiting and a good deal of prostration. I therefore put her on small doses of prussic acid combined with tincture of nuxvomica, which settled the stomach, and in the course of a day or two completely restored the appetite. During the second day I was also able to procure for her use a large water pillow which extended from the nates to the neck, and was of the greatest possible benefit, as the comfort it gave alleviated the irksomeness of maintaining the same posture, and prevented restlessness. The night's rest was secured by a hypodermic dose of 1-5th grain of hydrochlorate morphia qualified with 1-100th grain of sulphate atropine.

Being now relieved from all pain and taking her meals with a good appetite as well as a moderate proportion of stimulants, the case went on so favourably that the wound in the soft parts had united before the end of the second week, with the exception of a sinus at the bottom of which the probe detected a point of bare bone.

During the third week the air unfortunately escaped during the night from the small air-pillow. The displacement thus caused was followed by an access of what the patient herself called "mad pain." I then found it desirable to supplement the evening hypodermic dose of morphia with gr. xv of hydrate chloral to be given at two or three a.m. As the parts became hot and tender, I laid over them a piece of wet spongio-piline, and in view of her constitutional peculiarities I put her on the use of ioduret potassæ. This pain subsided in the course of a week with no other local bad result than the formation of another sinus below the patella. I then left off the hypodermic dose of morphia and atropine and substituted for it a double dose of the chloral hydrate, giving 15 grains at bed hour and 10 grains more if found necessary early in the morning. The sinus which then formed as well as that which more immediately followed the operation had closed before the end of January, when I discontinued the chloral as I thought it produced a lowering effect, and she slept well without it.

About the middle of February finding the parts were tolerant of pressure, I moulded on them at each side a piece of thick gutta percha softened in hot water and enclosed in a double layer of linen, by means of which they could be fastened on. I preferred this apparatus to a starch bandage, because if from an access of pain or tenderness, to which she was at that time still liable, it became irksome, it could be readily removed as well as re-applied. On the 26th February, she left her bed for the first time, after I had further strengthened the limb with a strong but narrow splint reaching from the trochanter to the heel, and secured to the limb at both places and also at two intervening distances.

From that time she began to move about the ward on crutches, and now she is able to take exercise in the open air.

She has gained flesh and strength since the operation, and her appetite is good, but her convalescence was for some time retarded by anomalous febrile attacks attended with palpitation of the heart, to which she had long been liable. They have now almost entirely ceased.

With respect to the limb as seen from the front it lies quite straight, viewed laterally the thigh makes with the leg an angle of  $168^\circ$  or  $170^\circ$  which can be lessened on flexion to about  $160^\circ$ . The patella adheres firmly to the subjacent parts, and she is able easily to raise the limb from the bed as she lies on her back, but it is evident that complete and general bony union has not yet taken place, though consolidation continues to make progress. The shortening is rather more than three and a-half inches.

## Hospital Reports.

### MIDDLESEX HOSPITAL.

WE have previously given some notes of the year's work at this hospital derived from the valuable reports of the Registrar's; we now add a few others. From the carefully compiled tables it appears that one hundred and twenty-three cases of acute and subacute rheumatism were under treatment during the year; 56 males and 67 females. Of these, 108 cases, 50 males and 58 females, were admitted during the year 1870. Three cases died; 13 remain under treatment. Of the 110 patients who left the hospital, reliable data were so far obtained as to the cardiac affection in 78. The details of the other cases were either incomplete or not sufficiently trustworthy for the purpose of drawing accurate conclusions from them. Of these 78 cases, 38 were males and 40 females. Recent

heart mischief occurred in 50 of these—in 25, or 67·7 per cent. of the males, and 25, or 62·5 per cent. of the females. Of the 78 cases, 28 were apparently unaffected by recent cardiac mischief, but in four of these there was old valvular disease.

*Complications.*—In 9 bronchitis, in 1 broncho-pneumonia, in 4 pneumonia, in 3 pleuritis, in 3 pleuro-pneumonia, in 9 tonsillitis, in 1 epistaxis, in 1 menorrhagia, in 1 epilepsy (to which, however, the patient had long been subject), in 2 hysteria, in 1 mania, in 1 peritonitis, in 1 enteric fever, in 6 albuminuria (believed in several cases to be due to embolism of the kidney), in 1 otorrhœa, in 1 diarrhœa, in 1 abscess in the axilla, in 1 acne, in 1 pompholyx, in 3 erythema, and in 2 herpes labialis.

*Family History.*—A reliable family history, so far as rheumatism is concerned, was obtained in 73 cases. Of these a history of rheumatism was traced in 38, affecting one or more members of the family. Of 27 cases in which the family history as regards nervous diseases were obtained, 9 were found to present the following history. In 2 families epilepsy was traced, in 1 epilepsy and mania, in 1 mania, in 3 "fits," the precise nature of which was not ascertained, and in one family one member was deaf and dumb and another very hysterical. In 5 of these cases a rheumatic family history was also present. The average total duration of illness of those patients who 9 cases were completed was 46·8 days.

*Treatment.*—The alkaline method of treatment was adopted in almost every instance. Exceptions are noticed in the tables. A narcotic was not unfrequently given to produce sleep, and during convalescence some tonic with or without iron.

The next disease of which full tables are given by the Medical Registrar is chorea, of which 11 cases were under treatment—1 male and 10 females. The average age of the patients was 14·7 years. Of this number 3 were discharged convalescent, 5 relieved, and 1 unrelieved. One patient died, and another remains in the hospital. Cardiac valvular disease was present in 2 cases, and doubtfully so in a third; and there was some cardiac abnormality of an indefinite character, such as irregularity in action of the heart, and roughness of the cardiac sounds, in 4 cases. There was a previous rheumatic history in both the patients who were affected by valvular disease of the heart. In 5 of the 11 cases a history of rheumatism was obtained. In 6 the patients had suffered from either one or two previous attacks of chorea. There was obtained a history apparently of epileptic convulsions in 3 cases. In 8 cases in which details were obtained, there was a family history, in 1 of rheumatism, and in 4 of nervous affections. A history of fright prior to the commencement of the symptoms was obtained in 3 cases; the exciting cause was doubtful in 6 others. Many of the cases were very obstinate. The average duration of the disease at the time the patients were admitted was about eight weeks. In the case which suddenly proved fatal the necropsy showed that there was considerable congestion of the membranes of the brain. The left vertebral artery contained a firm embolus about five lines in length, completely plugging the canal of the artery immediately beneath the lower border of the medulla oblongata. A similar plug protruded from the cut orifice of the carotid artery, just as it entered the cavity of the cranium. The brain was rather soft, and particularly the anterior part of the corpus callosum, the neighbouring parts of the hemisphere, and the pons varolii; but microscopical examination afforded no abnormal appearances. There were soft and recent vegetations on the mitral valve, and slight pericarditis. The spleen and kidneys were the seat of numerous embolisms of recent date.

*Health of London.*—In the Metropolis, last week, 1,938 births and 1,296 deaths were registered, the former being 236 and the latter 49 below the average. Zymotic or preventible disease caused 393 deaths, of which 232 were from small-pox, atal cases having increased in the southern and western districts.

WEDNESDAY, JULY 5, 1871.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

No more fitting opportunity can, perhaps, be taken than the very eve of the election to make a startling revelation.

It is high time the Fellows were informed of some of the proceedings of those who would exclude them from their proper sphere of action. We do not publish the information for the purpose of influencing the poll to-morrow, but to open the eyes of all the Fellows to the gross abuses that require redress, and we select the occasion that Fellows may, if they like, talk it over and take action. We propose, then, to explain the notice that has lately been given, of a Resolution having been passed, that all legal opinions taken by the College should be laid before the Council. It arose in this way—

On account of the disposition of Fellows to insist on their right to elect the College representative in the General Medical Council, it appears that the President and Vice-Presidents took Counsel's opinion, and presented a little bill of £25, which they wished to pass as ordinary law charges. Some of the members of the College Council seem to have thought such a bill of costs should be explained before the accounts were passed, and so far pressed their views that the officials were reluctantly compelled to give information. It then appeared that the money had been spent in obtaining Counsel's opinion that, *on the case put to him*, Mr. Quain was legally elected. The question was not as to the propriety of the high officials spending College money in such a manner, but as to whether such action should be concealed from the Council. If so, the Council must be impotent, and all the liberal additions made at the last few elections would still leave the government of the College in a state disgraceful to a free country and a liberal profession.

We ask the Fellows who will vote to-morrow, whether the facts we have taken upon ourselves to reveal are not more important to the interests of the College and of the Profession, than any statements that have been put forward in any quarter. They may enquire, but above

all they ought to act. The liberal members of the Council, who have done what they could, should be supported by new men of the same quality. When we find what is continually going on, we almost despair of the College being made what it well might be; but once more we would urge prompt action on the Fellows, assuring them that unless they are earnest and united their cause will be lost.

### POISONING BY CHOCOLATE CREAMS.

A VERY sad event of this nature has been investigated by a coroner's jury at Brighton. The following evidence, taken from a report in the *Brighton Examiner*, is of a kind to cause much alarm:—

"Dr. Letheby, Professor of Chemistry at the London Hospital, deposed that on Friday evening last he received from Inspector Gibbs a paper parcel, containing a wide-mouth pint glass bottle, and two small paper parcels. The bottle was tied over and sealed, and it was labelled, 'Stomach and its contents, with a piece of the liver, of a boy four and a-half years old.' Witness carefully examined the stomach and found it had been opened. It had a perfectly natural appearance, showing no sign of the action of any irritant whatever. In the bottle there were two ounces and a quarter of a brownish liquid, the contents of the stomach, which had a slight odour of chocolate, and the appearance of chocolate. In it he found some small pieces of meat, partially digested, a small piece of lettuce, and three or four grains of wheat—whole wheat. Witness had carefully examined them for poison, both mineral and organic. They were quite free from mineral poison, but they contained nearly a quarter of a grain of strychnia. Of the two other parcels to which witness had referred, one was labelled 'No. 1. June 13th, 1871. Received the enclosed from Charles David Miller.—W. Gibbs, Inspector.' The parcel contained several chocolates. There were four kinds—pink, red, white, and brown. He found the colouring matter to contain a preparation of alum and cochineal, not soluble in spirit. He found no trace of poison in the pink chocolates, but there was strychnia in the white ones—or in one of the white ones. The other parcel was marked: 'No. 2. June 13th, 1871. Received the enclosed from Miss Annie Meadows.—W. Gibbs, Inspector.' That parcel contained two kinds of 'chocolate creams,' rose, pink, and white ones. They were quite free from deleterious matter, and the colouring matter was different from the others. Witness had heard the account of the symptoms connected with the death of the deceased; they were those of poisoning by strychnia; and witness had no doubt, from the quantity of strychnia found in the stomach, that the child died from the effect of that poison. There was, in fact, enough strychnia in the stomach to kill a child of that age.

"By the coroner: Strychnia was not likely to have been used in the manufacture of bon-bons in any way. It was not used in the preparation of confectionery at all. It was used as a vermin-killer—to kill rats and mice, and so on."

It was shown that the Brighton confectioner purchased his chocolate creams from a London manufacturer, who had been in business thirty-two years, and the coroner thought this sufficient to exculpate him. At the same time it was admitted that rat-poison was purchased by the men employed in the manufactory, as also was cream of tartar, which is used in the process.

The coroner recommended the jury to give a verdict in accordance with the medical evidence as to the cause of death, and to say there was no evidence to show how the strychnia got into the creams. This was done. The jury

exonerated all parties, but suggested that there might be a little more care about using vermin-poison.

It will be understood from this by the public that a new danger of a terrible kind lurks in confectionery. The instances that have occurred of poisonous substances being used as colouring or flavouring ingredients were bad enough, but men hoped that first-class houses would not be guilty of such frauds. But here it would appear the integrity of manufacturer and vendor cannot protect us, unless they will at once banish the custom of poisoning the vermin. The mistake of a servant in using the vermin-poison instead of some other substance, may scatter death far and wide. Imagine the awful mistake of strychnia going into tons of bon-bons about to be scattered throughout the kingdom, possibly exported to all parts of the world.

We are decidedly of opinion that it is by no means justifiable to use poison for vermin or other purposes in any place where confectionery or other edibles are manufactured or sold. Admitting that the jury were but right to exonerate all concerned in this case, we maintain that its occurrence is so distinct a warning of the danger of some such accident, that should another case occur from such cause it will be wilful neglect on the part of those who use poison where bon-bons are made or stored.

If death itself having occurred is not sufficient warning, what is? The answer to that question will not, we fancy, be a pleasant one, should another accident happen.

---

## SCOTLAND.

### EDINBURGH.

**DR. CHRISTISON.**—About two years ago, several gentlemen in token of their great regard for Professor Christison, and of the eminent services he had rendered to the university, resolved to procure for the university a bust of him, executed while he was still in full vigour and vitality. The subscription in every case was limited to one guinea, and so rapidly did the contributions flow in, that in a very short time the list had to be closed, as the committee found they had too much money for the purpose they had in view. With the surplus funds it was resolved to present a *replica* of the bust to Professor Christison's family. On Thursday, Sir Alexander Grant as chairman of the committee of subscribers, formally presented the bust to the Chancellor and Senatus. This unprecedented honour conferred on Dr. Christison will, we are sure, be considered by every member of the profession as a just tribute of respect to that distinguished man.

**CRAIG v JEX BLAKE.**—Judgment has been given on the appeal by the defender in this case. The first division have unanimously rejected the appeal, sustained Lord Mure's ruling, and granted expenses to the pursuer.

## Notes on Current Topics.

### Protection from Poisoning.

THE antagonism between the Pharmaceutical Society and the Government continues in much the same stage as when we last reported progress to our readers. The Council of the Society, after the example of the Communist Government, obstinately maintain their neck or

nothing opposition to the Pharmacy Amendment Bill, although they must be aware that Mr. Foster has only to lift his finger to make it law, and although the honourable gentleman has distinctly told them that he will lift the finger if they don't consent to voluntary reform.

On the 24th of June, the Society's Council sent a memorial to the Privy Council asking for the withdrawal of the Bill on the ground—firstly—that the chemists don't like it; secondly, that doctors' surgeries ought to be included in its operation; thirdly, that the power of removing from the Register a chemist convicted of an offence under the Act is too stringent; fourthly, that the definition of a poison which should be subject to the precautionary regulations is too vague; fifthly, that the Irish Act does not enforce poison precautions; sixthly, that the precautions would increase liability to accident instead of diminishing it. This memorial was presented to Mr. Forster by a deputation, but produced a disastrous effect. Mr. Forster absolutely refused to listen to any arguments coming from a deputation which refused to amend and wished to destroy the Bill. He said that he had expected to hear the provisions of the Bill discussed, and perhaps improvements suggested; and, with a view to the consideration of suggestions, he had arranged for the presence of Mr. Simon and Mr. Jenkyns from the office of the Government draftsman. He should have been pleased to hear anything which might have been said by those desirous of improvement, but thought that there could not be useful discussion with a body of gentlemen who would only be content with the rejection of the Bill. He further promised that the Bill should not be read a second time before July 3rd. He referred to the Act, and remarked that the intention of the Parliament of 1868, that there should be compulsory regulations, was shown by the first clause, and he did not think that the views of the present Parliament would be different. He should be prepared to meet the opponents of the Bill if they would raise in Parliament the direct issue whether the legislation of 1868 should be revoked; but in any event, although the period of the year would be in favour of opponents to the measure, he must accept the issue, and, whilst conceding reasonable time, be understood as intending to press for the principle of the Bill.

In other words, Mr. Forster said that the Parliament which gave vitality to the Pharmaceutical Society wished for compulsory precautions. If the Society liked to surrender their authority as Guardians of Pharmacy, he might allow them to do so; but in any other event, he insisted on regulations, and would not even talk about any other proposition. The deputation wanted him to state what he would give them in the way of concession; but he desired them to ask for what they wanted, and he would consider whether he might yield it.

The Government is evidently very angry, and has taken an attitude of command, which they very seldom assume towards a public body, and which binds them to abate nothing of their orders.

We have already said that, in one point, we entirely concede the justice of the Society's representations, and we consider that it would be unjust and one-sided legislation which would compel chemists to set their houses in order, and allow medical medicine vendors to dispense in any way they liked. The memorial of the Pharmaceutical Council says, on this point, that the danger connected with powerful medicines is either, firstly, inherent to the poison,

or, secondly, it belongs to the person dealing with it. If the first presumption be accepted, the State should demand from all citizens the same compliance with regulations: to the second supposition we must emphatically object that there are no grounds for fixing this stigma either upon the Society we represent, or upon the general body of chemists and druggists. The unequal action of this Bill is strikingly shown in the case of Glasgow, where there are about sixty chemists and one hundred and twenty open surgeries kept by medical practitioners, and undistinguishable from the shops of the chemists in their appearance and in the business carried on. The deputation from Glasgow which waited upon the Council of the Pharmaceutical Society has most forcibly shown that the Bill would drive from the shops of the chemists to those of the surgeons all that numerous class of poorer customers requiring remedies that this Bill says may only be supplied by the chemist in a "poison bottle."

Inasmuch as we have not the least belief that anything which the chemists can do will defeat the Bill, we trust that the Council of the Society will, at the eleventh hour, have the sense to retreat from their untenable and unreasonable position, and evince a readiness to do their duty to the public, securing to themselves a "clear stage and no favour," which the Government is evidently disposed to give them.

#### Irregular Consultations.

DR. GORDON, of Dublin, has addressed the *British Medical Journal* in reply to the letter of "A Consulting Physician" which we published last week. The full text of the letter is not printed by our contemporary, but enough of it is given to show that Dr. Gordon contrasts favourably the social status of the Irish Profession with that of their English brethren. He says,—“In all matters of medical etiquette the Irish Branch of the Medical Profession is immeasurably in advance of the Profession in England,” and “such matters as partnerships—club attendances for sixpence or threepence per head, and all such other trade partnerships as are every week to be found in the pages of the *Journal* are utterly unknown to respectable practitioners in Ireland.”

This is, at least, a *tu quoque* argument, but so far as it goes we entirely concur with Dr. Gordon. The veriest drudgery of the beggarliest dispensary in Connaught is, socially and actually, superior to the miserable shop doctoring and contract physicking which Dr. Gordon characterises as existing in England. But we see no relevancy of that fact to the subject of consultation with quacks, beside which, as a crime against medical etiquette, the least reputable chandlery doctoring in England is a venial sin. We are not able to say how far such coquetting with medical pretenders exists in England, but we hope that the purism of Ireland in matters of professional honour, for which Dr. Gordon takes so much credit, will continue to vindicate itself, as it ought, against even the suspicion of palliating such proceedings.

#### Tea or —!

“A BREAKFAST table with ‘Simpson’ in the cream-jug, alum and potato in the bread, lard in the butter, and a decoction of horse-nails and willow leaves in the tea-pot, is not an appetising display of viands, and yet we are coming to it,” says the *Daily News*. “We might as well grow our

tea at home, if it is to consist of willow leaves. We have succeeded pretty well in manufacturing port-wine *without* grapes, and champagne *without* wine, and it is strange if we cannot—having once got the hint from them—improve on the rogueries of the heathen Chinese.”

The importation of caterpillars’ filth, rotten leaves, and iron filings, which last year was sold under different names, has been again publicly noticed by Dr. Letheby, with as little result as on a former occasion. Six hundred half chests, or about 30,000 lbs., have just been placed in the market, and part of it is, as we write, sickening the poor purchasers, who pay 3s. per lb. for what cost retailers—the papers inform us—from ½d. to ¾d. per lb.!

There are practical difficulties in stopping this trade, but the City authorities seem to be doing their best. But then the authority of the City does not extend far, and therefore the cargoes can be discharged outside the City jurisdiction.

#### Baby-Farming in Scotland.

BEFORE the Select Committee Mr. Wm. Cameron said, that he believed the rate of infant mortality was largely increased by the negligence of those who undertook the care of children. Baby-farming prevailed in Edinburgh and Glasgow to a very large extent, and he invariably found that the children were in a squalid, miserable, and emaciated condition, without proper food, and sometimes without a bed to lie down upon; while the nurses, in many cases, lived a life of gross intemperance. In one house at Portobello he found eight children under the care of two old women, and he had reason to believe there were many similar cases in Scotland. He had no hesitation in saying that children were taken in with the deliberate intention that, by a course of neglect, their lives should be sacrificed; and as in many cases a lump sum was paid down to the baby-farmer, this result was not long delayed. Dr. Cameron, of Glasgow, gave similar evidence. He expressed his belief that there was a great deal of criminal or culpable neglect which resulted in the death of the children which were accepted by baby-farmers. In cases where weekly payments were made for the children, it invariably happened that the amount paid was not sufficient to provide healthy food, and the child therefore had to put up with unwholesome food until it succumbed. The procurement of abortion prevailed very largely in Scotland, particularly in Glasgow; and he urged the necessity of compelling the registration of still-born children, and a system of inspection of all houses where children were taken in to nurse.

#### Liability of Druggists for the Effects of Counter Practice.

AT the Sheffield County Court last week, a saw carpenter sought to recover from a chemist and druggist, damages alleged to have been sustained through the administration of improper medicine.

The plaintiff was passing along the street when the defendant, who was near his shop door, asked him how he was. Plaintiff replied that he was not very well, upon which the defendant recommended him to have a penny-worth of his pills. He took the pills as advised, but received no benefit from them, and he informed the defendant of this as he passed his shop the day but one afterwards. The defendant thereupon said that plaintiff’s

liver was out of order, and told him he had better take some of his liver pills, supplying him with a box containing twenty, and instructing him to take six per day. This he did for three days, and on the fourth morning he took the remaining two. After commencing work on the fourth day he was taken very ill while at work; he became very weak, his tongue was swollen, his teeth loose, and salivation set in. So ill did he become, that he fell down and had to be taken home. A surgeon who was sent for, attended him at his home for nearly a fortnight, and gave it as his opinion that his illness was the effect of extreme salivation. He then went into the Sheffield Hospital, and for sixteen weeks was unable to work. It was contended that the defendant, if he represented himself as skilled in diseases such as he said the plaintiff was suffering from, ought to have given him proper directions in reference to the medicine, but simply said, "try my pills."

The judge said that the law was that every person who held himself out as following any skilful employment was bound to bring to the exercise of it a reasonable amount of skill. This applied to medical men, but not to chemists and druggists, who were simply sellers of drugs. There was a case in which a person went to a blacksmith to have a tooth drawn, and the latter broke his jaw. He sued for damages, and the Court held that there was no cause of action, because the man should not have gone to a blacksmith under such circumstances.

A chemist and druggist could not administer medicines for profit. If a man would be so great a fool as to go to a chemist and take any pills that he might give him, it was his own fault. The matter having been argued at some length, his Honour decided that there was no case for the jury.

The ordinary practice of mankind was not to go to chemists and druggists as if they were medical men, but to go to a medical man first, obtain his advice, and then go to the chemist and druggist for the drugs that had been prescribed. In the present case the plaintiff first went to the chemist and druggist, and took the pills which he recommended. It might be that the plaintiff had been injured by the pills, but in his opinion that made no case for the jury. There was no skill required by a chemist and druggist, who did not hold himself out as a possessor of skill. It was the same as if the plaintiff had taken pills which he (the Judge) had recommended as very valuable for his complaint. He (the Judge) would not be liable under such circumstances, he should direct the jury to find verdict for the defendant.

#### Adulteration of Lard.

THE *Canada Pharmaceutical Journal* recounts that some time ago, the stock of prepared lard being exhausted, a quantity was procured from a respectable pork dealer. It was beautifully white; so much so, that the writer was led to question his ability to produce anything equal to it. The first trial was in preparing ointment of nitrate of mercury. The colour, when the mercurial solution was added, was the reverse of citrine, indeed, decidedly saturnine, developing in a short time to a full slate colour. Surprised at this unprecedented result, the usual precautions having been taken as to temperature, etc., the lard was suspected, and, on examination, was found to contain a large proportion of lime. Some time after, being in conversation with a lard-renderer, a hint was dropped as

to the relation of lime to colour, when the information was confidentially imparted that a common practice among lard dealers was to mix from two to five per cent. of milk of lime with the melted lard. A saponaceous compound is formed, which is not only pearly white, but will allow of the stirring in, during cooling, of twenty-five per cent. of water. So much for appearances.

#### The Proposed Appointment of an Irish Union Apothecary.

THE Commissioners, alluding to this subject in their Irish Poor-law Report, recommend supplementing the present provisions of the law by a defined mode of appointing the officer, and by the establishment of a Board of Management representing the several unions combined. But it would be impossible to do this on so large a scale as that contemplated by the recent order, and they now think that several groups of unions, each with a central depot, and each with a separate officer, appointed and superintended by a representative board of management, would work very well, and relieve them from a responsibility as the immediate supervising authority which they ought not, perhaps, to undertake.

These establishments, with the assistance of experts in chemical analysis, might answer the purpose effectually of securing reliable drugs for the treatment of the sick under the Poor-law and Medical Charities Act.

They would not be disposed, however, to exercise these powers in regard to unions which did not consent to be combined for the purposes in question.

#### A Grudging Retraction.

THE *Lancet* is unable to deny the gross blunder it has committed; but, unfortunately for its own reputation, it seems unwilling to make an honest confession. Mr. Stoddart's letter, which we quoted from the *Pharmaceutical Journal*, is referred to in last week's *Lancet* in that limbo to which it consigns so many half-rejected communications—its "Notices to Correspondents"—apparently in the hope that there it will be overlooked. Still we will take the grudging retraction for what it is worth, and will rescue it from our contemporary's "dust-heap," as we have heard that limbo called, and thus show that we are only actuated by a desire to promulgate the truth. The *Lancet*, pretending to address Mr. Stoddart in its Notices to Correspondents, as if he had written to it, confesses it cannot name a substance which gives a spectrum coincident with that of blood. Of course it cannot; and thus it has been compelled to acknowledge, what it ought in common honesty to have avowed, its hasty and ignorant pretensions in attempting to depreciate the value of the micro-spectroscope, as a means of discovering blood.

#### Proposed Establishment of Government Village Hospitals in Ireland.

IN their Twenty-first Annual Report, the Commissioners called attention to the remarkable degree of immunity from epidemic disease observed in Ireland since the close of the famine period. If an epidemic influence were to set in, the fever hospitals attached to the workhouses, which have superseded the county fever hospitals almost universally, would be found in many unions inadequate to meet a serious outbreak of fever, not only as to the

number of beds, but more especially as to their remoteness from populous localities in which an epidemic might appear.

The Commissioners are of opinion that no more effectual way of protecting this country against future invasions of epidemic disease, and of affording in ordinary times effectual medical relief to the sick poor residing at a distance from the workhouse hospitals could be adopted than by establishing, where it may be necessary, what are in England called "Village Hospitals," attached to the dispensaries, and placed under the care of the Dispensary Medical Officers in each case. In other words, we would, if funds were forthcoming, advocate adding to the Dispensary in populous districts remote from the workhouse, buildings comprising at least two wards for either sex, capable of containing from five to ten beds each, according to the circumstances of the district. The additional cost of such an establishment to the union would consist of the salary and maintenance of a nurse tender, and a fair addition, if requisite, to the salary of the medical officer, and the providing of beds, bedding, &c., for the patients.

As regards the cost of the buildings; such auxiliaries to the present system of Poor-law hospital relief would, in our opinion, have the first claim on whatever part of the surplus of the Irish Church Fund might become hereafter available for such uses, and if an advance on security of that fund could at once be made, it would be put to immediate use in a considerable number of unions.

### Homœopathic Conversions.

DR. PAYNE, in the last issue of the *Monthly Homœopathic Review*, publishes a paper "On the Dose," the tendency of which is so directly in the line of a recantation of infinitesimalism, that it seems worthy of quotation: Dr. Payne says—

"We ask then, not only the question, what dose will cure (*perhaps, in many cases a high dilutive dose will cure if time be allowed*), but we ask what dose will cure most quickly . . . the nearer we get to the physiological power of the drug, so we get the quickest curative power. . . . Determine the smallest quantity which will produce the physiological effect, then the dose, just short of that, *is the most efficient curative dose*. . . . Loyalty in homœopathy consists not in high dilutionism."

It would be a satisfaction to be made aware whether this is bad Homœopathy or good allopathy? It is altogether too sensible to come within the pale of homœoquackery.

### A New Vesicant.

IN the *Australian Medical Journal*, Dr. Wylie, Surgeon to Hamilton Hospital, states that, during his residence in the island of Java, he found that a vesicant was extensively used in medical practice the name or existence of which he had never before heard of.

Like cantharides, tinct. andol andol is obtained from a fly. It is found in China in great abundance. It is of a dull, dirty leaden colour, about twice the size of a Spanish fly, and in general appearance not unlike a large Australian blow-fly. The tincture is the only preparation he had seen. The Dutch apothecaries prepare it from the fly, which they import in considerable quantity from the Celestial Empire.

The tincture of andol andol is most convenient as a blistering fluid, being painted on the part to be vesicated, just as tincture of iodine is used. It dries on the skin in a few seconds after application, and vesicates most effectually in from three to four hours. Before applying it, however, the skin of the part to be blistered should be washed first with soap and water, and then with common vinegar.

Ever since he first heard of it until now, Dr. Wylie had used tinct. andol andol and never found it fail.

### The Royal Commission on the Contagious Diseases Act.

The *North British Daily Mail* notes letters which have been received by members of the committee of the Association for the Repeal of the Contagious Diseases Acts. From these it appears that the Royal Commission have, by a majority of thirteen to six, reported in favour of the repeal of Acts 1866 and 1869. Three of the prominent members of the association for promoting the extension of these Acts—Admiral Collinson, Sir Walter James, and Prof. Huxley—are stated to have voted with the majority, and to have made speeches to the effect that they came on the Commission believing the Acts were wise and beneficial, and have been convinced by the evidence laid before it that they were mistaken.

### Toe Disease.

A SAN DOMINGO despatch of the 6th ult. furnishes the following:—"The toe disease is spreading. Over a thousand persons afflicted with it are in hospital." This is believed to be a sort of leprosy, a disease prevalent in various forms among the negroes of the West India Islands. In the English islands it is known as yaws, crab yaws, and cocobay. In some cases the extremities become shrivelled and gradually decay, finally dropping off joint by joint. In other instances the disease is confined to the soles of the feet, commencing with a small hard kernel, from which fibrous-like radiations grow. The foot swells and becomes misshapen, and when a sore is formed, the loss of the limb, and in many cases of life itself, follows. In adults these disease are considered incurable, but in young children a very singular remedy is adopted. A hut of bamboo, covered with cocoa-branches, is built. A sort of couch, on which the child can partially recline, is placed inside, with the seat about three feet from the ground. On the floor in front of the couch a fire is lighted, and over it, at some distance above the fire, an iron pot three parts filled with water is placed. The child is laid upon the couch, and the foot affected with yaws is put into the water, which is kept almost at boiling heat. The child remains in this position for about a fortnight, some person attending to its wants day and night and looking after the fire. The negroes call this killing the yaws. It is well known that a complete cure is effected by this singular mode of treatment. This dreadful disease is certainly communicated by contact. The negroes, who fear it worse than the small-pox or cholera, warn their barefooted children never to walk in the tracks of another person when the soil is damp, as it is their firm conviction that the disease is generally acquired in this way.

### The Fever in Buenos Ayres.

THE official return to date gives the total number of 13,403 deaths. But other returns, from private and impartial sources, confidently state the total to be over 26,000. In one block of low buildings seventy corpses were found in such a state that no one could bury them, so the whole block was burnt, bodies and all; and a whole family of five were found dead and deserted after many days in a shut-up house.

### Sectarianism in Medicine.

AN agitation, which is fraught with the most serious considerations as regards the administration of the Irish Medical Charities, and the interests of those engaged in their working has been set on foot within the last fortnight, in connection with the vacant office of dispensary medical officer in Kingstown. A very lengthened manifesto has issued from the pen of a local ecclesiastical dignitary, which propounds ideas alike repulsive to common sense and justice, and to medical equality. The object of the agitation thus inaugurated, is to show that no medical man should be allowed to take medical charge of a dispensary, unless he is of the same religion as his patients, and as a necessary consequence that the whole of the medical charities of Ireland should be handed over to persons possessing one religion. It is sought to give a colour of reason to this monstrous dogma by arguing that craniotomy is an abomination to the Roman Catholic Church, and that, therefore, anyone who might, could, would, or should, under any circumstances, consider that operation advisable, is unfit to do obstetric duty amongst the Irish poor. The *sequitur* of this argument which the author of the manifesto does not avoid, is that all obstetricians who craniotomise, are guilty of spiritual murder.

We know nothing of sectarian quirks of this sort. There fittest use is to get up election steam, to heat the angry passions of the mob, and to foster hatred, envy, and malice between neighbours and fellow men; but we do know that, practically, craniotomy is almost unknown in dispensary practice, and it is plain that however frequent the cases for its employment, it never could be possible if the religious views of the patient or her family forbade. But it deeply concerns us that the pestilential aroma of religious venom which has been instilled day by day into all things Irish, should now intrude itself into the charitable medical succour of the sick poor. The Good Samaritan put behind him the religious bigotry of the Levite, whose sectarianism forced him to "pass by on the other side." Let us hope Poor-law medical officers will be allowed peacefully to follow the same good example, and that common compassion will yet prove superior to the dogmata of any sect, whether Orange or Romish.

### Pantaleoni v. the "Tablet."

THE *Tablet* has to pay £250 damages for libel on our very good friend and able contributor, Dr. Pantaleoni. We have not much sympathy for the proprietor, inasmuch as the libel complained of was persisted in in spite of denial. It was to the effect that the doctor had reinstalled two convicts in office at the hospital of San Gennaro. As Dr. Pantaleoni informed the editor that at the time of the alleged event he was an exile from Rome, one might naturally have looked for a withdrawal of the statement.

This act of justice was, however, refused, and our Italian *confère* appealed to an English court. Dr. Vaughan, of the *Tablet*, thus brought to book, admitted there was no foundation for the libel, and apologised. It is to be regretted that the *Tablet* should not have been ready to confess its error until compelled to do so. Dr. Pantaleoni's vindication is, however, complete.

### Vaccino-Syphilis.

AT the concluding meeting of the Session of the Royal Medical and Chirurgical Society, the report on this subject was presented. The committee a limit that the cases they were appointed to investigate have been accurately described by Mr. Hutchinson and Mr. Warren Tay.

THE Liebig's Extract of Meat Company slaughtered 88,869 head of cattle last year.

THE annual election of Councillors in the Royal College of Surgeons of England, takes place to-morrow.

DR. LANKESTER, during a recent inquest, made the startling announcement that over 300 dead children were found in the streets of London every year.

THE health of Paris has been much improved by cleansing the sewers with solutions of phenic acid and chloride of lime.

AN Examination of Candidates for Commissions in the Medical Department of Her Majesty's Army, will be held in London on the 9th of August next.

ON Thursday last a marble bust of Dr. Christison, the distinguished professor of materia medica in the University of Edinburgh, was presented to the Library of that Institution, by Sir Alexander Grant, on behalf of the contributors.

No doubt there will be a keen competition for the new appointment, announced in another column, of Resident Assistant-Physician to the new St. Thomas's Hospital. The latest day for receiving applications of candidates is next Tuesday week.

AT an inquest held in London, on Friday, on the bodies of twins, it was shown that death resulted from the carelessness of the chemist, who supplied poisonous powders instead of rhubarb ordered by the surgeon. This is but another instance of the abominable way poisons are stored in apothecaries' shops.

A HORRIBLE atrocity reaches us from China. On the 4th of May a ship, with more than 600 coolies on board, caught fire, great suspicion existing as to the cause. The captain and crew escaped, but 600 coolies, with the hatches battened down, were left in the hold, in the language of an eye-witness, "to stew in their own fat." Not one of the 600 escaping this fearful death.

THE *Gazet. Farm. Ital.* advocates the addition of chloral hydrate to cod-liver oil; it renders it much less

nauseous, and prevents the night sweats of the phthical patient, induces sleep, and creates appetite. It is prepared as follows:—"10 gr. pure chloral hydrate crystals with 190 gr. cod-liver oil, digested in a sand-bath with gentle heat. Dose, 6 table spoonfuls daily."

The worthy Treasurer of St. Thomas's Hospital, Sir Francis Hicks, has fallen foul of the Borough Rifle Volunteers, in not allowing them to form a guard of honour to Her Majesty upon the opening of the new buildings. It appears to be a rule that when any public pageant or royal ceremony takes place, and the volunteer force is called into requisition, the corps whose head quarters is nearest the scene is selected for this privilege, and when, upon the present occasion, the colonel of the regiment wrote to ask why a distant company had been chosen, Sir Francis replied, that as the First Surrey had done it before they should do it again. The Borough Rifles naturally felt aggrieved, and our contemporary, *The Volunteer*, remarks that the authorities of the Hospital have acted in a most questionable manner.

The annual meeting of the Female Medical Society was held last week, the college is intended to be self-supporting, but this point has not yet been attained, and funds are required to provide a museum of illustration and a library of reference, as well as to consolidate the institution by means of a Royal Charter. The report stated, that during the session ninety-eight had availed themselves of the Society's Obstetrical College, fifty-one of these were single, twenty-six married, and twenty-one widowed wives or widows of clergymen or medical men. Most of them attended the lectures with a view to practising as skilled midwives. Two ladies had been recommended by the committee for responsible professional positions in connection with the Birmingham Lying-in Hospital; two of the past students, Mrs. Thorne, and Miss Chaplin, are now studying for the degree of Doctor of Medicine at Edinburgh. A resolution was passed condemning the present system, by which the whole medical teaching of the United Kingdom is monopolised by a few privileged schools; this being, it was urged, injurious alike to medical teaching, the profession, and the public at large. It was also resolved that, in view of the probable opening of the Edinburgh University to lady students, the Society should confine itself to the establishment of a high-class school of obstetrics for women.

A GENTLEMAN who signs himself "Edward Haughton, M.D." and is, we believe, the proprietor of a hydropathic establishment, was reported by the daily press as having, at a meeting of vaccino-phobiacs at Exeter Hall, spoken against the protective efficacy of vaccination. He replies in a letter to the *Post* in which the following passages occur:—

"The Medical Profession, as a body, is not answerable for the tone of some journalists, who seem to conclude that if vaccination be admitted to have any protective virtue, the compulsory law is completely justified. . . . I would say that in order to justify so arbitrary a measure we ought to be in a position to affirm that vaccination never does harm. The answer to this is obvious; there are several thousand persons now actually ill in London from re-vaccination. . . . Careless vaccination has often propagated hereditary disease, and the man who has the

effrontery to assert the contrary is quite ignorant of the literature of the subject. . . . Vaccination is a preventive of the individual to a large extent, but all epidemics prove that it fails to protect the community."

The reasoning here is uniquely vaccino-maniac. Truly, it is not reasonable that we should be expected to find argumentative brains for such people. Nevertheless, we must observe that compulsory vaccination can neither be justified because it has "any" protective virtue, nor condemned because it "never" does harm. No one with an unsoftened brain would suggest that vaccination should be enforced if it only protected a few persons, or that it should be abandoned if it were conclusively shown (which it has not been) that it occasionally did harm. The matter is one altogether of balance between the good achieved and the harm risked, and as the undeniable good is, in this case infinite, and the risk of injury infinitesimal, it is the most contemptible display of puerility to special plead as Dr. Haughton does.

To complete the absurdity, we may observe that, it is perfectly unproven that vaccination has in any number of cases "propagated hereditary disease," and glaringly false that it "fails to protect the community."

But how can one argue with persons who are utterly impermeable to facts or to reason?

## Literature.

### TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. Vol. XXI.

[SECOND NOTICE.]

#### *Diseases of the Organs of Digestion.*

THE first case, by J. D. Hill, is entitled, "True Diaphragmatic Hernia with Stricture of the Oesophagus." This is a remarkable case, as the patient lived to be fifty-four, and yet the hernia of the stomach and part of the duodenum had been congenital, and placed in the right pleural cavity. In addition, a stricture of the oesophagus, close to the stomach had formed within the last year of the man's life, due to schirrus growth. Our space forbids of our entering further into the details. Nos. 3, 4, and 5, by Drs. Clapton, Murchison, and Peacock, are examples of fatal bleeding from the opening of small vessels in the stomach; at least, in two of them, for in the last case it was the splenic artery was opened. All these cases are worth perusal. No. 9, by J. W. Legg, M.D., who was indebted to Sir W. Jenner for the opportunity of giving the case, is a truly remarkable one which we wish we could give details. It is entitled, "Congenital Constriction of the Ileo-cæcal Orifice; Dilatation of the Ileum; Retention of Fruit Stones in Jejunum and Ileum." Even with this state the patient lived to be thirty-two years of age; but we must refer our readers to the volume for the details of this unique case. No. 14, by H. W. Fuller, M.D., is entitled, "Polypoid Growth in the Bowel, giving rise to Intussusception." It would seem that the patient, a girl of twenty-one, had laboured under the disease from the age of twelve. It is not easy, we must say, to understand how it could have existed so long. In addition to the polypus which caused the invagination, there were as many as thirty others higher up in the ileum. The actual cause of death arose from ulceration and perforation. No. 17, by J. J. Bristowe, M.D., is entitled, "Peritoneal Cancer." We notice it as it was a case in which the diagnosis must have been very uncertain. Towards the last the patient's

mind was quite heavy; almost comatose. The author expresses his wonder at this; for the brain, he says, was all but healthy. When, however, we refer to the account given we find there was an excess of serum in the sub-arachnoid tissue, and "marked congestion of pia mater." We believe that such a state is quite capable of affecting the mental powers.

Diseases of the liver form a sub-section in this portion of the volume. Amongst the cases we notice several where syphilitic growths affected this organ. We hope this idea is not being carried too far. One, for instance, No. 19, is entitled, "Syphilitic Cirrhosis of the Liver." The organ was atrophied. Now, we do say that the syphilitic poison may not have attacked it, but, as the patient had led an irregular life we do say that these habits had, most probably, very much to say to this state. On reading further on the report of the committee appointed to investigate this case, we now find that they did not consider this liver syphilitic; but curious enough they look upon its etiology as still obscure. Again, No. 21, by Henry Morris, is entitled, "Syphilitic Disease of the Liver, associated with Amyloid Disease of all the Viscera and Peritonitis, in an imperfectly developed girl, aged twenty years." It has rarely fallen to our lot to find a case more strangely misinterpreted than this one. Here is a girl with no history whatever of syphilis, and born of healthy parents, with no marks on her person. She remained healthy, too, till her eleventh year, when she gets ophthalmia. This was followed by sore throat, deafness, ozæna, ascites, peritonitis, and disease of both the kidneys and liver. In fact she was a mass of disease, all of which is attributed to syphilis!! For ourselves we cannot believe this to be the correct view. The whole history of the case is opposed to it. It is infinitely more probable that the poor girl was a delicate strumous child, and that one and all the diseases were due to this predisposition. We have seen all the diseases this patient had, and without any syphilis. The case is a very good example of the way in which the judgment is led astray when certain notions are taken up as they seem to us to be in London at the present time, in reference to the poison of syphilis. But the subject is too extensive to pursue further at present. Case 23, by J. Murray, M.D., is entitled, "Extravasation of Blood into the Liver, Ovaries, and under the Serous Surfaces, in a case of death from Ante-partum Hæmorrhage." We notice this case as the author considered the cause of fatal bleeding as being obscure. The patient, it is to be observed, was unmarried; a point which is not dwelt on; though we believe it capable of modifying largely everything connected with pregnancy. Nor is a word said about the placenta; though the case may have been one of placenta prævia; at least, the symptoms are very like that complication. It would have been well had a committee investigated this case closely. The next two cases, by Drs. Murchison and Tuckwell, are examples of gall-stones, one in the bile duct and the other the hepatic duct; they are each of interest in their way and will well repay perusal. No. 27, by J. F. Payne, consists of two cases of "Suppuration in the Liver, consequent on irritation in the Vermiform Appendix." In the first of these cases a pin was found in the appendix; but it does not appear to have caused any acute inflammation. In the second case ulceration of the appendix existed; though no foreign body was found.

#### *Diseases of the Genito Urinary Organs.*

The first two cases, by Drs. Roberts and Murchison, are entitled, "Villous Disease of the Kidney, and the same affecting both the Kidneys and Bladder. In each case there was hæmaturia, and in one the passage of the blood-clot down the ureter gave rise to the symptoms of calculus. In neither does it seem as if there was any malignant growth, though from the state of the mucous membrane it is possible, had the patient lived longer, such would have been found. No. 3, by T. Whip-

ham, M.B., consists of two cases where most extensive disease of the kidneys existed, of the cystic variety, and yet where there was almost an entire absence of symptoms during life. No. 6, by A. Leared, M.D., is a case of "Cancer of the Kidney and of the Liver." The patient—a member of the Profession—was sixty-four years of age, and suffered for several years from diffused abdominal pain, this was followed by bloody urine, and then a tumour was detected over the left kidney, and this was painful on pressure. Finally, the liver enlarged and also became tender. The examination disclosed malignant disease of the left kidney, with the liver full of Farr's tubercles. It is not to be wondered at that this case was very obscure, and for a long time considered to be one of calculus of the kidney. Nos. 8 and 9, by Drs. Dickinson and Crisp, are each examples of sacculated kidney; one having calculi, and the other none. We notice them as each, during life, presented very great difficulty of diagnosis, and we need not say how much the character of the physician depends on this point. Nos. 10 and 11, by Drs. Cayley and Dickinson, are examples of "Acute Renal Dropsy, without Albuminuria." We are long familiar with this fact, in connection with the anasarca of scarlatina; but it is as well that it should be re-stated. At Berlin it would seem as if the presence of albumen were the exception, and not the rule, as with us. No. 12, by Sir H. Thompson, is "a Case of Vascular Tumour of the Bladder possessing unusual characters." The fungus which grew in the fundus of bladder had assumed the pedunculated form, and each—for there were two—was the size of a fig. No. 14, by Drs. Holmes and Williams, is entitled, "Cast of a Calculus, which weighed twenty-five ounces, and which was removed from the bladder after death." This is a very interesting case, and occurred in the person of Sir T. Adams, who lived in the time of Charles the Second. The patient was eighty-one years of age. Independent of the great size of the stone, there are other points in the patient's history which will well repay perusal. There is also an engraving of the stone itself, and of the exact size it had reached. No. 18, by H. W. Fuller, M.D., is a case where "Hair and Cheesy Matter passed by the Urethra." This is a very well detailed, but at the same time, most obscure case. It occurred in a female of fifty; but we cannot refer to it more here. No. 21, by H. Arnott, is a very elaborate report, we may call it, on "Fifty-seven cases of Cancer of the Uterus." To those interested in this particular branch of medicine, the report must prove most useful.

Amongst the diseases of the osseous system we notice several of much interest. Thus, No. 4, by W. F. Clarke, is an example of recovery after compound fracture of the skull, with loss of brain-substance. The patient was a boy of twelve, and the fracture extended into the orbit. The injury was followed by hernia cerebri. Yet, with all these symptoms the boy seems to have made a complete recovery. No. 5, by G. Lawson, is a still more remarkable case. The title, all we can give, will afford some idea of the nature of the case: "Sudden appearance of a large Elastic Pulsating Tumour, immediately over an opening in the Frontal Bone, which was made eighteen months previously, by the Trephine, for the removal of depressed fragments of bone pressing into the substance of the Brain; rapid subsidence of the swelling immediately on the outbreak of a copious Herpetic Eruption." The only point we should notice is whether the swelling of the brain had any connection with the herpetic eruption. We think not; but that the subsidence of the swelling was clearly due to the fact that the tumour was punctured, and gave exit to a large quantity of serous fluid.

In the section on "Tumours" we observe a number that possess a high degree of interest; but our limits forbid us to do more than refer to them. In the conclud-

ing part of the volume will be found some interesting examples of disease as it appears amongst the lower animals. Amongst these we would particularly notice the paper by Dr. Crisp "On Calculi." This may be called a *résumé*, and contains not only a great deal that is curious, but also what is highly practical in its bearings. It proves too, contrary to the opinion of many, that calculous complaints occur with great frequency in some parts of India, and we must repeat that this essay is, in every aspect, valuable.

We cannot conclude our brief, and necessarily imperfect, notice of this volume without adding that we have read its contents with very great interest and improvement, and, valuable as many of its predecessors have been, we believe we are correct in saying that the present exceeds all the others in the important matter it contains, and in the great accuracy of detail of most, if not all, the cases. It is scarcely necessary to add that the volume is admirably got up, and illustrated by many engravings and plates; some of the latter being coloured.

PUNCTUALLY on the 30th June Braithwaite's "Retrospect" \* reached us, and afforded the opportunity which we never like to miss of looking through its pages and noting the skill displayed in the selection of its contents from our own columns and those of our contemporaries. The alphabetical synopsis of the most practical articles in the volume is a most interesting feature. It shows at a glance what are in the opinion of two able editors, the chief indications of treatment published by different writers during the half-year.

## Correspondence.

### THE BRITISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have the honour to request publication of the accompanying correspondence, and to subscribe myself.

Your most obedient servant,

SAMPSON GAMGEE,

18 Broad street, Birmingham, June 26, 1871.

WILLIAM D. HUSBAND, Esq., F.R.C.S., J.P., *President of the Council of the British Medical Association.*

MY DEAR SIR,—The more carefully I consider the notices of motion for the next annual meeting of the Association, published in your name in the *British Medical Journal*, the more deeply am I impressed with the sense of their great importance.

The laws of the Association are, I believe, twenty-seven in number, and of these no less than twelve are affected, several radically, by your notices of motion. I think our associates might be assisted in forming a correct estimate of the changes you propose to effect, if you deemed it advisable to direct the publication in an early number of the *Journal* of the laws as they are now in force, and as they would be if your notices of motion became law.

It appears that you propose that the secretary shall no longer be a member of the council or of the committee of council, but that such officer shall henceforward reside in London, and devote the whole of his time to the business management of the Association, and of the *Journal* office. Without venturing to express any opinion on the advisability of effecting such a change, I submit that it is not merely an administrative alteration, but deeply affecting the fundamental principles on which the Association was founded.

When it was deemed advisable to change the name of our body from the Provincial to the British Medical Association, it was generally felt to be in the interest of the profession to maintain the independence of the Association from those

metropolitan influences which have hitherto centred so powerfully in the medical corporations, and have militated, in favour of the few, against the general interest of the great body of practitioners throughout the country.

The events of late years have not detracted from the cogency of arguments formally held to be valid in favour of an independent organisation of the profession.

It has been stated that as at present administered, the British Medical Association has become practically a great joint-stock enterprise for the publication of a weekly journal which absorbs nearly the whole of the Association income. Hitherto the independent action of the secretary, a medical practitioner residing in the provinces, and having a seat in the council and the committee of council, has secured to the great body of practitioners an official representative, not under the control of the *Journal*; but if the secretary is to be reduced practically to the position of a paid clerk residing in London, and charged with the business management of the *Journal* office as well as of the Association, he must be subordinate to the editor, or, in business matters be co-ordinate with him in authority; the latter alternative would be incompatible with good government, while the former would eventually lead to such a centralisation of power in the editor of the *Journal* as to render him practically for the time being, the master of the Association.

I do not observe that you contemplate making any alteration in law 23, concerning the audit of accounts. Hitherto it has been held, though by no means unanimously, that the independent position of the secretary and the editor acted, to some extent, as a check in the financial arrangement. If, however, you propose to make the secretary a clerk in great part subordinate to the editor of the journal, an official public auditor of the accounts could scarcely fail to give very general satisfaction, the more so since no official denial has been given to the rumour current on very good authority, that the funds of the Association have lately suffered materially from the action, which I do not attempt to characterise, of one of its subordinate servants.

The British Medical Association has adopted a policy with the avowed intention of influencing the legislature in the reform of the Medical Acts, five of our most distinguished associates amongst the leaders of the medical profession in the three kingdoms have recently resigned all connection with the Association on a question vitally affecting its management. Is it too much to presume that you have taken these facts into full consideration with your colleagues on the committee of council before giving the notices of motion to which I have referred? If this assumption be correct, is it not reasonable to look to you for a statement of the reasons which have led you at so critical a period in its history, to propose such extensive organic changes in the management of the Association.

Since your proposals open up the whole question of the government of our body, it is essential that full opportunity be given for discussion, and I suggest that you give notice of a special meeting during the approaching annual meeting for the discussion of your notices of motion.

I intend forwarding copies of this communication to the medical journals, but shall not do so before the 27th inst., so that I may transmit with it a copy of any reply with which you may favour me.

I am, dear Sir, faithfully yours,

SAMPSON GAMGEE,

18 Broad street, Birmingham, June 24, 1871.

MY DEAR SIR,—The most important alteration in the laws, of which I have at the request of the committee of council, given notice in the journal will only be proposed at Plymouth, if the members agree to the proposal which will be submitted to them to improve the business working of the Association and *Journal* office.

The committee of council will fully submit to the council, and if the council approves, to the meeting, the reasons which have induced it to recommend the proposed changes in the working of the Association. These changes can in no way lead, as you fear to metropolitan or editorial supremacy, as the election of the governing body by the members generally (so vast a proportion of whom reside in the provinces), will not be affected. The meeting must decide when the discussion on the report of the council shall be taken.

I had, before receiving your note, taken steps to have the

\* "Retrospect of Medicine, January to June 1871." Edited by W. Braithwaite, M.D., and James Braithwaite, M.D. London: Simpson, Marshall, and Co.

proposed alterations in the laws printed in the *Journal* in a form which will render them more intelligible to the members.

I am, yours very truly,

W. D. HUSBAND.

36 Bootham, York, June 26, 1871.  
Sampson Gamgee, Esq., F.R.S.E.

MY DEAR SIR,—I lose no time in thanking you for prompt and kindly courteous acknowledgement of mine, 24th inst.

I regret that I cannot attach the importance, which I generally do to your opinions, to the statement, that the changes you propose "can in no way lead to Metropolitan or editorial supremacy, as the election of the governing body by the members generally (so vast a proportion of whom reside in the provinces) will not be affected."

The government of the Association professedly based on representative principles, has so far as I am informed, no parallel in any representative assembly or society in the world. The nominally supreme council has no control over the Association, as a distinguished associate once cogently put up, during a recess of 861 days in the year. Whatever be the theory of our constitution—a most legitimate matter for difference of opinion, the practical effect is scarcely open to question. Take for instance the ensuing year, hopefully looked forward to by medical reformers. Who will wield the power of the Association when its president resides at Plymouth, the president of the Council at York, the treasurer at Bath, and the members of the council be scattered in units over the three kingdoms, while 37 Great Queen street, or some such central office in the metropolis, will be the head quarters of the editor, and of his subordinate officer, who will combine the functions of business manager of the *Journal*, and of secretary of the Association? A fact not to be forgotten is, that no provision is made in the laws, or in your notices of motion either for a public audit or for substantial security being given by paid servants who may have the handling of the whole income of the Association.

I am happy to think that this discussion is not with yourself personally, for whom I have always entertained most sincere respect. You have confirmed my anticipations that the notices of motion of the most important alterations of laws have been given at the request of the committee of council, and I therefore hold myself at liberty, to promote, or take part in, such measures as may be deemed necessary for bringing to an issue on public grounds, questions, which however solved, cannot fail to exercise an important influence on the future of the Association, and on the best interests of the medical profession.

According to previous intimation I forward copy of our correspondence to all the medical journals.

I remain, very faithfully yours,  
SAMPSON GAMGEE.

18 Broad street, Birmingham, 26th June, 1871.  
To WILLIAM D. HUSBAND, Esq.

#### CAUTION TO IRISH ASSISTANTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I have been constantly in the habit of giving strong advice to gentlemen educated in the Irish medical schools, not to come to England as assistants without first acquiring a practical acquaintance with *apothecary's work*, which is required from every medical assistant in England. Hospital dispensing is of no use, because it is wholly a different thing from private dispensing in England. I have written emphatically on this point in my "Via Medica."

As a melancholy result of disregarding this advice, I desire to relate what has just occurred.

A young gentleman producing excellent testimonials from Dr. Shuldham Henry, of Belfast, Professor Andrews, Dr. O. Hare, Dr. Gordon, Dr. Dill, Dr. Seaton Reid, Dr. Hodges, and two Presbyterian ministers, obtained an appointment near London, with a client personally known to me as a gentleman of kindly disposition and considerate temper. With the testimonials mentioned above was one from the proprietor of a Medical Hall in Belfast, speaking of the candidate's skilful treatment of disease, &c. On his arrival, my client found the young gentleman so wholly incompetent to attend to his dispensing, that he was compelled at once to dismiss him, as he was about to put two drachms of sp. ammon. aromat into his mixture, for a child of three months old! The assistant had no idea, moreover, of the manipulation necessary in the

surgery of a general practitioner in England. This is a flagrant case which will cause great inconvenience to my client, but greater suffering and inconvenience to the young gentleman engaged as assistant. I desire to make it as public as possible through your columns as a caution to those who think that they can learn dispensing and apothecary's work *after* they have entered upon their duties in England.

I am, dear Sir, yours faithfully,

J. BAXTER LANGLEY, LL.D., M.R.C.S., &c.

50 Lincoln's-inn-fields, London.

#### ABORTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Women appear to look upon abortions as trifles scarcely worthy of note, entirely ignoring the fact that health may be permanently damaged. A gunner's wife for a length of time went on washing, thrice changed her lodgings whilst suffering from hæmorrhage, associated with partially detached blighted ovum, and at last giving up when too late, she died of exhaustion. Causes at various times assigned—washing, wringing clothes, over-lifting, carrying children, boxes, baths, fenders, trays, marches, travelling, specially by rail, falls, fatigue, dancing, romping, running, squabbling; agüe, bronchitis, cholera, constipation, debility, epilepsy, fevers, syphilis; early marriages, weakly histories, extremes of temperature, over nursing, rapid pregnancies, tooth extraction, taking emetics or purgative; fright induced by fire, shipwreck, earthquake, storms, seeing death, deformities, exciting dramas, Blondin pretending to fall off the high rope, mental emotion, hearing bad news, or loud noises, specially firing, sudden fear induced by horses, dogs, drunkards, wolves, ghosts, rats in a cupboard, or on board-ship, having a pocket picked, walking at the Crystal Palace, standing at the Queen's Drawing-room, going over the Woolwich Arsenal, toiling up the steps at Dover; ill-treatment, blows, sea-sickness, habit, worry.

Your obedient servant,  
F. R. H.

#### OBITUARY.

##### THE LATE PROFESSOR ANSELME PAYEN.

WE hear with regret the death of this eminent French chemist, whose name will doubtless be familiar to most of our readers in connection with food analyses. He was born in Paris, January 17th, 1795. He was elected member of the Institute in 1842. In early life he had the management of a factory where the sugar was extracted from beetroot. Afterwards, after having had charge of other chemical works, he became Professor of Industrial Chemistry in the Paris School of Arts and Sciences. We may mention amongst his scientific and chemical researches his work on the "Conversion of Starch into Dextrine and Grape-sugar," and his investigations on Diastase. He experimented on the physical and chemical properties of different vegetable tissues, and the chemistry of the nutrition of plants. He wrote on the distinctive characters of animal compared with vegetable tissue, and made experiments on the gastric juice. At different periods of his life he made various investigations on gun cotton, the potato disease, manuret, and other subjects. He was quite recently one of a Special Commission, nominated to make a report on disinfectants, and was very active in the matter of food-supply which the recent lamentable war rendered so necessarily urgent and interesting to Frenchmen of science and ability.

##### THE LATE MR. SIMS SHAW.

AMONGST the many victories lately claimed by death from our ranks the name of the late Mr. Olive Sims Shaw, of Stockport, deserves mention. He was articled at the commencement of his professional career to a general

practitioner of Stockport, and was a pupil at the Stockport Infirmary, finishing his curriculum at Guy's Hospital. After taking M.R.C.S., he became Assistant Medical Officer to the Gloucester Lunatic Asylum, and was subsequently appointed House-Surgeon to the West Derby Union, where, overworked by the present epidemic of typhus fever, he, after a short illness, succumbed to the disease. He was amiable in his deportment towards others, unflinching in the performance of his duties, and undebatingly conscientious in all things. He gave great promise for future years.

#### THE LATE DR. DAUN, OF EDINBURGH.

THE Profession has lost one of its most venerable members in the person of the late Robert Daun, M.D., M.R.C.P., F.R.C.S., Deputy Inspector General of Hospitals, &c., who has recently died at the advanced age of ninety-one. He was born at Insch, in Scotland, April 16th, 1785, being the eldest son of the parish clergyman. He was educated at the Elgin Grammar School, and afterwards became a medical student at Aberdeen. When only nineteen he became a member of the London College of Physicians, and entered the army as assistant surgeon at an early age. He was almost immediately drafted to India, being first in the 22nd Light Dragoons and afterwards in the 59th Foot. Returning to England in 1814, he exchanged into the Scots Greys, and served at the battle of Waterloo and with the army in France. He again went to India in 1820, and finally returned to England in 1825. In consequence of his vast experience in the treatment of cholera, he was chosen Deputy-Inspector General of Hospitals, in which capacity, on the occasion of the great epidemic of 1831-32, he went to the infected districts, and received the thanks of Government for his services on this occasion. He was frequently consulted on cholera, and once restored two apparently hopeless cases by saline injections. He retired some time since, residing successively in London, Aberdeen, St. Andrew, and, at the time of his death, at Edinburgh.

### Medical News.

**British Pharmaceutical Conference.**—The meeting for the present year will be held in August, at Edinburgh, in the Craigie Hall, St. Andrew's Square, under the presidency of Mr. W. W. Stoddart, F.C.S., F.G.S. On Tuesday, the 1st, at 10 a.m., the President will deliver an address: the reading and discussion of papers on pharmaceutical subjects will then commence, be continued in the afternoon till 4.30, and be carried on during Wednesday; an adjournment from 12.30 till 2.0 taking place each day. Gentlemen engaged upon any investigation, are reminded that papers are expected to be sent in to the secretaries a few days before the Annual Meeting, accompanied by a short abstract for insertion in the local and other newspapers. Authors are specially requested to send the titles of their papers to either of the general secretaries two or three weeks before the Annual Meeting. The subjects will then be appropriately advertised, and thus full interest be secured. The objects of this Association of pharmacologists and chemists and druggists are—(1) to increase the common stock of pharmaceutical knowledge; and (2) to promote friendly intercourse amongst those engaged in pharmacy. In addition to the other means of attaining these ends, the conference annually presents to members a handsome octavo volume of 500 or 600 pages, containing the proceedings at the yearly meeting and a report on the progress of pharmacy, or year-book, comprising abstracts of papers on pharmacy, materia medica, therapeutics, and chemistry, and new preparations, processes, and formulæ, published at home and abroad during each year. Nearly the whole of the conference funds are devoted to the production of this book, no pains being spared to make it the desk companion of the year, and an invaluable permanent work of reference for every chemist and druggist. Either of the honorary general secretaries Professor Attfield, 17 Bloomsbury square, London, W.C., and Mr. R. Reynolds, 13 Briggate, Leeds, will give further information.

**Another Monstrosity.**—The American papers chronicle the birth of a new "two-headed nightingale" with but one body, two heads, four arms, two perfectly developed legs and feet on one side, and on the other one large imperfectly formed leg with eight toes upon the foot, and presenting the general appearance of the "consolidation of two legs into one." One head sleeps while the other is awake; and, while one head with its corresponding leg or legs is convulsed with infantine grief, the other smiles sweetly upon and coos at its nurse. This "infant phenomenon" has been "interviewed" by several intelligent reporters from the New York papers, and the physicians are of opinion that it will probably live.

**Apothecaries' Hall, London.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, the 29th June, 1871:—Charles Clay, M.R.C.S., of King's College, London; William Goodson, of the Westminster Hospital; Robert Alexander Lithgow, Downpatrick, Ireland, of Guy's Hospital; Horace Mansell Mayburr, M.R.C.S., of St. Thomas's Hospital; Edward Rice Morgan, of King's College, London; George Holthy Pinder, M.R.C.S., Manchester School of Medicine; and Frederick Skaife, of St. Bartholomew's Hospital. On the same day John Walter Scott, student of Guy's Hospital, passed his primary professional examination. At the recent competitive examination for the prizes in botany, given annually by the Society of Apothecaries to medical students who are in attendance on the second summer session of their medical studies, the successful candidates were:—First, Sydney Howard Vines, of Guy's Hospital, a gold medal; second, Edward Markham Skerritt, of University College, a silver medal and a book.

**Southampton.**—The deaths from small-pox remain about stationary thirteen as again fourteen of previous week. The guardians and magistrates seem to be quite unable to get on comfortably. A long report in the *Southampton Times*, of a scene between the mayor, medical officer, and master of the workhouse, seems to show that the authorities are rather pugnacious. We would suggest to all parties the propriety of ascertaining their respective legal rights, before attempting to enforce what they fancy them to be, and in all cases to keep their tempers. Dr. Hearne writes to a local paper to the effect that the authorities comply with the law as they understand it, without possessing, so far as can be seen, a particle of knowledge bearing upon its effective execution. He adds "it is admitted that the arms of patients have been scratched by hundreds, without any examination of results; it is further affirmed, incredible as it may appear, that uninformed people have been advised by their medical attendants that they themselves were competent to distinguish the true, genuine cow-pox from the spurious! This being an admitted fact; what legitimate ground of complaint can be preferred against uninformed authorities should they adopt the cheapest mode of vaccination for the public, and thereby effect an enormous saving to the ratepayers? If there has not been strict compliance either with the letter or the spirit of the Vaccination Act will the ratepayers endorse the conduct of the guardians, in the payment of hundreds of pounds for work so executed?"

**Cholera in Russia.**—According to the latest reports from St. Petersburg, up to June 12 cholera was still persisting, although in a modified and less deadly degree. By last reports from St. Petersburg, there were 79 cases of cholera from 29th May to 11th June, of these, 32 recovered and 38 were fatal. Number of cases under treatment June 11th, 143. Although, however, cholera has in a great measure decreased, it may again advance. From the 20th to the 27th of May, there was a decided increase of the epidemic, the number of admissions to the hospitals increasing to 21, double that of the preceding weeks. The deaths in this week were 9. During the three following days the deaths were three. On the 30th there were 32 cases under treatment. Cases of *foubroyant* cholera were rarer, and the disease yields more easily to treatment. The epidemic continues however, although diminishing, may at any time again extend. Among the conditions favourable to its spread must be ranked the humidity of the atmosphere. The weather, however, has cleared up according to our last reports. The total number of cases from August 29th, 1870, to June 12th, 1871, inclusive, are 4,622, of which 2,609 recovered, and 1,845 were fatal. We may now look forward with some faint shadow of certainty to a favourable termination of the outbreak at no very distant epoch.

## Gleanings.

### Spontaneous Generation.

LET us dwell, for a moment, on a still nobler use of the microscope. In the hands of Dr. Beale, a distinguished English physician, it has done what all the philosophers, and all the theologians, and all scientific talent combined, had previously failed to accomplish. It has demolished the materialistic and atheistic doctrine of "spontaneous generation;" just as the discovery of an apparently insignificant fossil, the "*Assterolepis of Stromness*," in a little far-off seaport of the Orkneys, by the lamented Hugh Miller, gave the death-blow to the no less atheistic "*development theory*," so interestingly set forth in the "*Vestiges of Creation*," a book which most of you have probably already nearly forgotten. It is impossible to give you any very definite idea of how Dr. Beale upset the spontaneous generation theory with his microscope, and his book showing "how to work" it, without going into a history of the development of this theory and its supposed facts, from the great Schwann, with whom it may be said to have originated, through Robin, and the French school, to Darwin and Darwinism. Suffice it to say, that Darwin erected his atheistic temple on what he terms the "primordial form." But Beale proves, by his microscope, and its skilful use, that there is no such form, and that therefore this temple is founded on sand or something even less substantial. He proves that there can be no development from a primordial form or vegetable cell into an animal, because the microscope shows that all vegetable cells have double walls, while animal cells have single walls; while it gives this further confirmation—that, if you give *organic* nourishment to a double-walled or a *vegetable* cell, it dies, whereas *inorganic* food causes it to spring up and grow. The reverse happens with the single-walled, or *animal* cell. All this is a matter of sight, not of speculation; what not only Dr. Beale, but any other microscopist may see. Thus we perceive how wonderfully, how mysteriously God manifests His truths unto us; how intimately blended are the interests of science and religion, and how absurd the efforts of those who, from a want of appreciation of scientific investigations and truths, have sought to array them in antagonism.

"Who would suppose," says Dr. Acland, in his inaugural address before the British Medical Association, "that the question of spontaneous generation, so keenly debated from a very early period, to our own year and day, need have any bearing on practice? Yet see how the observations of Pasteur are connected with the questions of infection, nay, more, of supuration, and (as shown to be probable by Prof. Lister) of surgical treatment. It would, indeed, be a great point if we could prove that no germs, carriers of disease, spontaneously originate, but must always come from a progenitor-cell. If so, there would be just a hope that some disease might be effectually stamped out." It is not too much to expect, I think, that the microscope will, ere long prove this. From an address "*On the Objects and Aims of Medical Science*," in *New York Medical Journal*, May.

### Extract of Meat.

THE "*Extractum Carnis*," known as Liebig's, is now extensively employed in medical practice. Now and then doubts are expressed relative to the nutritive value of the commercial extracts, and, occasionally, undesirable effects follow their administration. It is well known that the extract, whether prepared in the open air by the Liebig process, or *in vacuo* by the Borden method, can contain no albumen. The albumen is coagulated, and therefore excluded during the manufacture, so that the extract consists, as shown by E. Reichart's analysis, of

|   |       |       |
|---|-------|-------|
| Water separable at 110°C.               | - - - | 16    |
| Mineral constituents                    | - - - | 18.20 |
| Nitrogen                                | - - - | 9.51  |
| The extract is rich in potassium salts. |       |       |

Dr. Kemmerich has recently published in *Schmidt's Jahrbucher*, a detailed account of the physiological effect. An estimate of the nutritive value of the extract just referred to given.

He found by experiments on living animals, that *extractum carnis* in the form of soup, also meat broths and gravies of ordinary concentration, and free from seasoning, produce in the stomach active hyperemia of its mucous membrane, especially at the gastric follicles. Hence, he concludes that extract

of meat increases the activity of the follicles and hastens the secretion of gastric juice.

There is, moreover, a noticeable change in the character of the cardiac pulsation. The throb becomes more frequent, much stronger, arterial tension is increased, the pulse is made full and more rapid. He noticed also that a person by taking a little over one hundred grains of meat extract in the morning, experiences a slight elevation of temperature of the body above that of another person in substantially the same condition, and this elevation is followed by a corresponding depression.

The increase of temperature may be attributed to the increased circulation of the blood and consequently augmented oxidation of the tissues.

The extract of meat affords nutriment, but its improper use may be very injurious.

Dr. Kemmerich's study of the nutritive value was conducted by means of experiments on two dogs of the same birth and weight, subjected to the same vital conditions. To the food of one the mineral salts of meat extract were added, to the food of the other an equal quantity of common salt. The food was for both "*animal albumen*" separated from the aqueous solution of the muscle of the horse. The dog fed on the meat extract and albumen soon weighed more than the other. In the course of six weeks the dog fed on salt was hardly able to stand, while the other was bright and energetic.

The conditions were then reversed with very remarkable results. In a fortnight the reduced dog was fully restored, and in four weeks excelled the other in bodily vigour.

Dr. Kemmerich concludes that the extract of meat is a true restorative stimulant, with the further advantage of affording elaborated material for the formation of tissues.—*Bowdoin Scientific Review*.

## NOTICES TO CORRESPONDENTS.

DR. MACKIE has kindly furnished us with "Statistics of Venereal Disease in the Army," a portion of which we hope to give in our next. These Statistics will, we opine, be of considerable value just now.

STUDENT.—The Annual Distribution of Prizes at St. Mary's Hospital, will take place to-morrow at four o'clock.

DR. DAVID DUMFREES, Inspector General of Hospitals, was on Monday last, invested by Her Majesty, the Queen, with the honour of knighthood.

The following communications are in type, and will appear, if possible in our next:

Dr. Letheby, "On the Purification of Water."

R. Hanslip Sers, "Further Hints how to make Vaccination more Efficacious."

R. Uniacke Ronayne, "On the causes and cure of Prostatic Stricture."

J. L. Milton, "On the Treatment of Eczema."

J. Morgan, "On the Nature of the Venereal Poison."

## BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Half-yearly Retrospect of Medicine. Edited by Drs. W. and J. Braithwaite. London: Simpkin, Marshall, & Co.

Selected Obstetrical and Gynecological Works of Sir James Y. Simpson, Bart. Edited by J. Watt Black, M.D. Edinburgh: A. & C. Black.

Rapport sur L'Ambulance de l'Ambassade d'Autriche-Hongrie.

The Medical Jurisprudence of Insanity. By J. H. Balfour Browne, Esq., Barrister-at-Law. London: J. & A. Churchill.

The Half-yearly Abstract of the Medical Sciences. Edited by W. Donnell Stone, M.D. London: J. & A. Churchill.

Women and Doctors, or Medical Despotism in England. By Mrs. Hume-Rothery.

The Westminster Review; Detroit Review of Medicine; Boston Medical Journal; Woodhull's Weekly; Science Gossip; Practitioner; Journal of Mental Science; British Journal of Dental Science.

## VACANCIES.

Royal Orthopædic Hospital, London. Resident House-Surgeon and Apothecary. Salary £100, with residence and partial board. (See advt.)

St. Thomas's Hospital, Westminster. Resident Assistant Physician. Salary £100 per annum with board and residence. (See advt.)

Middlesex Hospital. Lectureship on Physiology to the Medical College.

St. Peter's Hospital for Stone, London. House-Surgeon. Salary £50, with residence and partial board.

Metropolitan Free Hospital. Assistant Physician. Honorary.

Hackney Union. Dispenser. Salary £100 per annum.

Farnham Union. Medical Officer for the Aldershot District. Salary £50.

Blackburn Infirmary. House-Surgeon. Salary £80, with board.

Suffolk General Hospital. Physician. Honorary.

Broadmoor Lunatic Asylum. Assistant Medical Officer, increasing salary, commencing £175 per annum. (See advt.)

## APPOINTMENTS.

ANDERSON, T. M'C., M.D., Consulting Physician to the Glasgow Institution for the Deaf and Dumb.  
 CAMPBELL, A. C., M.B., Surgeon to the Royal Infirmary, Dundee.  
 CARTER, B., M.R.C.S., Surgeon to the Eastern Dispensary, Bath.  
 DRYSDALE, C. R., M.D., M.R.C.P.L., has been elected a Physician to the Metropolitan Free Hospital.  
 DUDLEY, J. G., M.D., Physician to the Metropolitan Free Hospital.  
 EDDISON, J. E., M.D., Physician to the General Infirmary, Leeds.  
 MERGER, N. G., M.D., Medical Superintendent of the East Riding of Yorkshire Lunatic Asylum, Beverley.  
 OWEN, Mr. D. C. LL., Ophthalmic Surgeon to the Children's Hospital, Birmingham.  
 PRICE, Mr. C. W., House-Surgeon at University College Hospital.  
 RICHARDS, D., reappointed Medical Officer to the Brighton Infirmary.  
 ROBERTS, Dr. F. T., Assistant-Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.  
 SHAW, T. C., B.A., M.D., Lecturer on Mental Diseases at St. Bartholomew's Hospital.  
 SMYTH, E., M.B., Joint Resident Medical Officer to the Royal Infirmary, Dundee.  
 WADDY, J. P., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the Crossbeg Dispensary District of the Wexford Union.

## Marriages.

BOULOER—DENHAM.—On the 23rd ult., at her father's residence, 30 Merrion square, Dublin, by special licence, E. Vaughan Boulger, B.A., to Lizzie, second daughter of John Denham, M.D.  
 KERR—GIBSON.—On the 29th ult., at St. Peter's, South Kensington, N. S. Kerr, M.D., to Eleanor Georgina, only daughter of Edward Gibson, Esq., of Ballinerry, county Antrim.  
 SOUTHEY—WOODCOCK.—On the 29th ult., at Holy Trinity, Westminster, Anthony G., younger son of A. Southby, Esq., M.D., of Bulford House, Wilts, to Eliza C., younger daughter of W. Woodcock, Esq., of Bessborough street, Belgravia.  
 SWANBOROUGH—DUCHESS.—On the 29th ult., at St. Giles-in-the-Fields, William Swanborough, of Upper Norwood, to Eliza Maria, widow of Robt. Duchesse, M.D., of Woodford.  
 TAIT—STEWART.—On the 28th ult., at All Saints', Wakefield, Lawson Tait, F.R.C.S.E., F.R.C.S.Ed., of Waterloo street, Birmingham, to Sybil Anne, eldest surviving daughter of William Stewart, Esq., of York House, Wakefield.  
 WALKER—HETHERINGTON.—On the 22nd ult., at Christ Church, Bootle, George Charles Walker, M.D., to Louisa Ann, daughter of Walter F. S. Hetherington, Esq.

## Deaths.

ASBURY.—On the 21st ult., Jacob Vale Asbury, M.R.C.S.E., of Enfield, aged 79.  
 CRAWFORD.—On the 16th of May, at Dhurmala, Punjab, John Duncan Crawford, M.B., Surgeon-Major 2nd Bengal Cavalry.  
 DUNDAS.—On the 25th ult., Robt. Dundas, M.D., of Gloucester place, Hyde park, formerly Assistant-Surgeon 60th Regiment, for many years Physician to the British Hospital at Bahia, and afterwards Physician to the Northern Hospital, Liverpool.  
 EDMONDS.—On the 15th ult., Henry Edmonds, M.D., Staff-Surgeon H.M.'s Ship "Dædalus."  
 HAWETT.—On the 21st ult., Wm. Hawett, M.R.C.S.E., of Wigan, second son of Thos. Hawett, M.R.C.S.E., aged 31.  
 KYNSEY.—On the 23rd ult., Josiah F. Kynsey, L.K.Q.C.P.I., R.N., son of T. B. Kynsey, M.D., of Athy, Co. Kildare.  
 LAMBE.—On the 20th ult., at Torquay, Lacon Wm. Lambe, M.D., of Henwood, Dilwyn, Herefordshire, aged 73.

## The Medical Press and Circular

## OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

NAVAL MEDICAL DEPARTMENT, ADMIRALTY,  
 SOMERSET HOUSE, 1st July, 1871.

## NOTICE OF EXAMINATION FOR ENTRY OF ASSISTANT-SURGEONS IN THE ROYAL NAVY.

NOTICE IS HEREBY GIVEN that a COMPETITIVE EXAMINATION for the Admission of Assistant-Surgeons into the Royal Navy will take place at the University of London, Burlington Gardens, on Wednesday, 9th August, 1871, and following days, at 10 o'clock.

Candidates must present themselves at this Department on Monday, 7th August, 1871, bringing with them the various Certificates of Qualifications specified in the Regulations of the 24th June, 1871, when, should they be found in all respects eligible, they will be permitted to appear for Examination.

A. ARMSTRONG, Director-Gen-ral.

## APOTHECARIES' HALL, BLACKFRIARS.—

The next EXAMINATION in ARTS will be held at the HALL on FRIDAY and SATURDAY, the 29th and 30th SEPTEMBER, 1871. A Syllabus of the Subjects for Examination may be had on application.

An Examination in ARTS will again be held in the month of JANUARY, 1872.

R. H. ROBERTSON, Secretary to the Board.

## ST. THOMAS'S HOSPITAL MEDICAL AND SURGICAL COLLEGE.

THE ACADEMICAL SESSION for 1871 and 1872 will commence on MONDAY, the 2nd OCTOBER, in the new Buildings on the Albert Embankment, Westminster Bridge.

To enter, and for further particulars, apply to R. G. WHITFIELD, Medical Secretary at the Manor House, St. Thomas's Hospital, Newington, Surrey, S.E.

## ST. THOMAS'S HOSPITAL—APPOINTMENT OF RESIDENT ASSISTANT PHYSICIAN.

THE GRAND COMMITTEE OF GOVERNORS are prepared to receive applications for this appointment, to which will be attached a salary of £100 per annum, with furnished rooms and commons in the Hospital.

Candidates, who must be members of the Royal College of Physicians, or Medical Graduates of a University of the United Kingdom, not less than 25 years of age, are requested to send applications, not later than the 18th July, under cover to the Treasurer, at this office, No. 13 St. Thomas's street, S.E., where further information may be obtained.

28th June, 1871.

A. TRITTON, Treasurer's Clerk.

A RESIDENT HOUSE-SURGEON and APOTHECARY IS REQUIRED for the ROYAL ORTHOPÆDIC HOSPITAL, 315 Oxford street. He must be M.R.C.S. and L.A.C., or possess the certificates of Medical and Surgical Qualification of some British University, College, or Corporation by Charter, and be registered according to the Medical Act. Salary, £100 per annum, with lodging and partial board. Apply by letter, addressed to the Hospital, with Testimonials, &c., immediately.

ARMY MEDICAL DEPARTMENT,

27th June, 1871

AN EXAMINATION OF CANDIDATES for Commissions in the Medical Department of Her Majesty's Army will be held in London on the 9th AUGUST next; Candidates having the necessary qualifications to practise Medicine and Surgery under the Medical Act, and who are unmarried and not under twenty-one, nor above twenty-eight years of age, are eligible to attend. Applications for admission to this examination should be made in writing without delay to the Director-General of the Army Medical Department, War Office.

(Signed) T. G. LOGAN,

Director-General.

## BROADMOOR CRIMINAL LUNATIC ASYLUM.—

There is a Vacancy for a MEDICAL OFFICER, who must be legally qualified to Practise Medicine and Surgery, and unmarried. Salary, £175, increasing annually by £5 up to £200 per annum with furnished apartments, coals, gas, and attendance. Applications in the first instance to be addressed to the Superintendent, Broadmoor, Wokingham, Berks, not later than the 8th JULY.

Dated July 1st, 1871.

## ROTUNDA LYING-IN HOSPITAL, DUBLIN

Consulting-Physician—Alfred Hudson, M.D., F.K. and Q.C.P.I.

Consulting-Surgeon—Robert Adams, M.D., F.R.C.S.I.

Master—George Johnston, M.D., F.K. and Q.C.P., &c.

Assistant-Physicians—T. More Madden, L.K. and Q.C.P., &c. Alexander Taylor, L.K. and Q.C.P., &c.

Secretary—J. G. Strickland, Esq.

This Hospital, the largest Chartered Clinical School of Midwifery in the British dominions, contains one hundred and thirty Beds, twenty-five of which are appropriated to the Diseases of Females.

An Obstetrical Museum, containing upwards of five hundred Preparations, and a Library, are attached to the Hospital.

Clinical Instruction in Midwifery, and the Diseases of Women and Infants, is given daily.

The Pupils are Privileged to attend the Cow-Pock Institution, Sackville street, and York street.

The Lectures are recognised by the Royal College of Surgeons in Ireland, London, and Edinburgh; the King and Queen's College of Physicians; the Apothecaries' Hall of Dublin and of London; the Army and Navy Medical Boards; and all the other Licensing Bodies.

The Diploma from this Hospital is recognised by the Poor-law Commissioners as a qualification in Midwifery for all Hospitals and Dispensaries under their control in Ireland.

The Intern Pupils, of whom there is only a limited number, have each a separate bed-room, with the use of a sitting-room.

Two Courses of Lectures are given yearly—the first commencing early in November, the second early in May.

Applications to be made to the Master, Dr. JOHNSTON, at the Hospital, Rutland square.

## CHURCH STRETTON PRIVATE ASYLUMS

FOR the UPPER and MIDDLE CLASSES of BOTH SEXES, are situated among the Shropshire Hills, Twelve Mile from Shrewsbury, on the rail to Hereford.

A great variety of MICROSCOPES, TELESCOPES, and OPERA GLASSES, MAGI and DISSOLVING VIEW LANTERNS, PHOTOGRAPHIC APPARATUS, CAMERAS, LENSES, &c., by the best makers. Address—Farringdon-street, City, London. Enlarged and Revised Illustrated Surgical Catalogues forwarded for six stamps.

# FOX'S PALATABLE COD-LIVER OIL

“PALATABLE” CASTOR-OIL,

AND “PALATABLE” COD-LIVER OIL WITH QUININE,

Are the Finest Oils so prepared, as to be really pleasant to the taste, whilst their medicinal properties are not in the least impaired.

From Robert Cryan, L.K.Q.C.P., L.R.C.S., etc., Physician to St. Vincent's Hospital, Dublin.

I have had the Palatable Cod-Liver Oil of the Messrs. Fox and Co. administered to several of my patients, and I am convinced that it has been of very great advantage to them. Some of my patients in St. Vincent's hospital, in whom the ordinary cod-liver oil in its natural state, or even combined with sulphuric ether, almost always produced unpleasant eructations and vomiting, found the Palatable Cod-Liver Oil, of the Messrs. Fox and Co. not only agreeable to the taste, but also easily retained upon the stomach. In that rather large class of cases where the use of cod-liver oil is indicated, but, in its ordinary form, found to disorder the organs of digestion, I believe the administration of the Palatable Cod-Liver Oil will be highly advantageous. I may add that the dose of the Palatable Cod-Liver Oil should be nearly double that of the ordinary oil. Hitherto, I have not had very many opportunities of prescribing the Palatable Castor Oil, but as far as my experience extends, I can report very favourably of it.

GEORGE W. FOX AND CO., London Depot, 8 Bury Court, St. Mary Axe, E.C. MANUFACTORY: CITY ROAD, MANCHESTER; and through all leading Wholesale and Retail Chemists.

Palatable Cod-liver Oil, 1s., 2s., 3s. 9d.; with Quinine, 2s. 6d., 4s. 9d. Palatable Castor Oil 6d., 1s.

## Original Communications.

### ON THE NATURE OF THE VENEREAL POISON AS TESTED BY DIRECT PROOFS AND PRACTICAL OBSERVATIONS.

By Mr. MORGAN, F.R.C.S.I., M.D., Univ. Dub.

Surgeon to Mercer's, and to the Westmoreland Lock Hospital, Dublin; Professor of Surgical and Descriptive Anatomy; R.C.S.I. &c.

IN THE MEDICAL PRESS of June 21st, 1871, I have quoted from Mr. Wallace's records a very remarkable case of artificial inoculation, producing in a healthy patient suffering from gonorrhœa only; the characteristic pustule, sore, and suppurating bubo of the soft or non-infecting type, followed in due course by constitutional signs, but with a total absence of the incubatory period supposed to precede the appearance of a true syphilitic sore; yet Mr. Wallace's experiments have been endlessly cited in works on venereal, as proving the necessary incubative period of the syphilitic virus, when inoculated (as it is too evident he did) on healthy patients. This case so frequently alluded to as an evidence of the incubation essential to true syphilis, is given by Mr. Wallace in the *Lancet*, July 8, 1837. He himself remarks that an inoculation on a healthy man produced a "primary in a month afterwards." But if the history he gives be examined, it is, I think, evident the sore was but a re-ulceration, and that the original inoculation practised on August 10th, shewed "a red line surrounding it" on August 14th. The inoculation was practised on a rubbed surface the size of a shilling. This is quoted by writers as an illustrative example of true syphilitic incubation, sore, and constitutional infection, and is much dwelt on by the supporters of the dual theory, as a valuable evidence; but it is remarkable when we pursue his comments that the very succeeding cases are totally subversive of this suggestion.

The next case given is one of inoculation on a healthy

man, August 19th, showing areola, &c., by the 24th, followed by constitutional signs.

Another case, August 6th, 1834, he inoculated a healthy man from a primary pustular sore. On August 8th the punctures had "caused inflammation and a white ulcer with a sharp edge;" and on October 28th constitutional signs showed themselves, and "the secondary symptoms though mild were clearly pustular."

Another case, March 3rd,† he inoculated a healthy man with matter from a suppurating bubo "at the moment of opening it." On March 5th each puncture produced inflammation; on May 8th, sore throat, and then pains, rash, &c.

While such cases as the last are so plainly recorded, it is to be regretted that they should not also be alluded to; while the first has been so very frequently called on to support the doctrine of incubation, which is entirely disproved by the latter.

The following direct proofs are very interesting, and afford important evidence as to the essential characters of the infecting sore. The pustules were identical with those produced from soft sores on auto-inoculated patients, or with those produced from irritated true hard sores on infected patients, or from the vaginal discharge of infected patients on others also infected. The phenomena are the same, the difference in the appearances seeming to be in Mr. Wallace's cases dependent on the virus being applied by a "cut," or by "rubbing off the skin," or by "a blister." But the type was that of the "tumid" secreting ulcer.

The proposal lately mentioned by Mr. Lee, that pustules occurred in syphilitic patients with ease, because of their peculiar constitution, is overborne by these experiments made so long before the question of duality or of syphilisation was introduced, and they are the more worthy of careful consideration as bearing on the present vexed question of the unicisty or the variation by descent of the venereal sores. Mr. Wallace's note books abound in cases of sores and suppurating bubos, followed by secondary

\* See *Lancet*, p. 616, vol. 2, 1836 and 1837.

† *Ibid* p. 617 and 62

symptoms; in fact it seems to have been the rule, as I hope to show in future remarks. The following experiments illustrate the production of pustules from secondary lesions, the sequence of constitutional signs, and the usual history of pustular or simple sores.

#### Case No. 2.

July 7.—Philip Wall, suffering from gonorrhœa of a week's standing and for the first time; he was inoculated on the right thigh with the urethral discharge of J. McManus, a syphilitic patient, in whom the gonorrhœa had been artificially produced, by passing down the urethra the gonorrhœal matter of another patient, J. K., aged nineteen (who had the gonorrhœa sixteen days on him at the time); P.W. was also inoculated on his left thigh, and at the orifice of his urethra, with his own gonorrhœal matter.

July 17.—These inoculations failed. He was now inoculated on the right thigh from the sore on the thigh of Richard Bradshaw (whose history is given below, and whose sores were of a secondary nature—Case No. 5), and on the left from the urethra, which Richard Bradshaw had also superficially ulcerated.

July 19.—All the punctures have inflamed, and each has formed a sort of vesicular pustule; the base is not hard.

July 20.—The spots are rather less inflamed: he says they are still painful.

July 21.—The spots are all encrusted, and have ulcers under the crusts, with well-marked areola.

July 28.—The bases of all are very tumid.

July 29.—All the sores remarkable for their tumidity of base.

August 6.—Ulcers are elevated, complains of soreness.

August 9.—Sores are elevated and could be sliced off with a knife,

September 5.—Sores on thigh are now healed a week; glands in left groin are swelling; feels weak.

September 19.—Left thigh has assumed a condylomatous aspect; tumour in groin; papular rash at back of neck.

October 6.—Has a mottled rash; small and brown scaly spots; left groin glands a little enlarged; sore on thigh healed.

November 23.—Superficial ulcer of both tonsils; hair falling, &c.

N.B.—In this case, the inoculations from a secondary ulcer of the thigh and from a superficially ulcerated urethral orifice which felt hard, produced the same phenomena in two to three days, they were introduced by "cuts." The rash appeared in seventy-four days from inoculation, the sores lasted about forty days.

His own gonorrhœal discharge failed, and that artificially produced in a syphilitic patient also failed.

#### Case No. 3.

July 19.—J. F. applied, labouring under an uneasy feel in his urethra and some in his testes. Applied matter from the sore on the thigh of Richard Bradshaw (Case No. 5), to his right thigh, and that from the urethra of Richard Bradshaw to his left.

July 21.—All have inflamed; have cut him on the common skin of the penis, and applied the matter from the sore on the back of the leg of J. McManus (a patient infected by a sore accompanied by a suppurating bubo).

July 24.—The extent of the spots on the thigh has increased; the pustules and scabs formed are superficial; the cuticle detached at the circumference; the spot at the dorsum of the penis, which was cut, has not inflamed.

July 26.—The areolæ are very tumid; the ulcers fully formed and cupped; have passed into urethra the matter from J. McM's leg, and the ulcers on the dorsum of penis of P. M. (which have been before described in the MEDICAL PRESS, June 21, 1871, as artificially produced).

July 28.—There is no running from the urethra.

August 7.—The sores are still painful, brown in colour, margin raised, tumid base; no running from urethra.

August 10.—The sores are increased in size, still

brownish, their margins raised, but their surface not so high; not so painful as before.

September 6.—The ulcers are now all healing, he has suffered much; the ulcers had an unhealthy phagedænic appearance; the new formed skin is callous looking. He says he has pains and stitches through him; the people are noticing he looks badly. He is married, but has not given any disease to his wife.

N.B.—In this case the effects of R. Bradshaw's secondary ulcer and of his ulcerated urethra are identical. On the third day the inoculations inflamed; on the fifth day pustules and scabs are formed; on the seventh day the areola is marked. The product of a secondary ulcer, and of artificially produced syphilitic sore, passed into the urethra was inert, producing neither sore or discharge.

By September 6th, forty-nine days after inoculation, the sores were healing, and cachexia commencing.

#### Case No. 4.

May 26.—John T.—, a man labouring under an epheloid eruption; applied a blister, and applied the matter of Richard Sheridan to the sore (the history of R. S. is that of a sore and suppurating bubo), the blistered surface being previously scraped with a lancet.

July 17.—No effect. Inoculated with matter of Richard Bradshaw (Case No. 5), in one part, with that from the orifice of the urethra; and in another from the ulcer on his thigh.

July 21.—Both seem inflamed, one more than the other.

July 25.—Both the inoculated spots have formed crusts, surrounded by areolæ; on raising these crusts excavated ulcers with a sharp edge and white superficies exposed.

July 29.—The ulcers are fully formed; superior white edge, sharp, &c. They have very much the appearance of secondary ulcers.

August 7.—The ulcers are dry and their surface raised; no pain or areola. *No further history is given, as Mr. Wallace's notes soon terminated.*

N.B.—In this instance the patient was suffering from no venereal disease. The first inoculation failed, though derived from a patient whose sore was accompanied by a suppurating bubo.

The second, derived from a secondary ulcer, and from a superficially ulcerated urethra succeeded, producing the characteristic appearance in four days, and perfect ulcers in twelve days. There was no incubatory period in this case, in which there was no antecedent history of syphilis, and where, unquestionably, the inoculative virus was derived from a secondary lesion, producing a pustule, "with crust," with "areola," and with "sharp white edge."

#### Case No. 5.

June 20.—Richard Bradshaw, æt. twenty-one, has an ulcer of a white colour, rather superficial on the left side of the corona; the edge next prepuce is red for fourteen days; and a gonorrhœa for a week; got both at the same time. Has had gonorrhœa twice before.

July 17.—Sore unhealed and gonorrhœa still continuing; the orifice of the urethra is superficially ulcerated, and has extended all round; it feels hard; the glands in both groins are swelled, but not much inflamed. He is covered with rash, which he says he has six or seven weeks; has two large thick crusts on the outside of his right thigh; removed the crusts and found it to be a granulating sore; with this P. W., the preceding case was inoculated on the thigh on the same day, July 17th.

July 19.—Penis less swollen; rash paler; sore on right thigh, healing fast, &c.

This case is remarkable as furnishing a secondary matter from the outside of the thigh, which produces a characteristic pustule in forty-eight hours followed by a sore, exactly as can be produced from the vaginal discharge of an infected female, (*Dublin Quarterly Journal*, August, 1870), on those already infected, yet in these instances the

exactly as can be produced from the inoculation of an infected female, (*Dublin Quarterly Journal*, August, 1870), on those already infected, yet in these instances the

recipients were not previously infected, as is evidenced by the regular succession of constitutional signs. Those who hold that a person suffering from constitutional syphilis (as this man was, for he had rash six or seven weeks), cannot be again the subject of a syphilitic sore; must admit that the sore on the penis was not "a true syphilitic sore" and as the phenomena of both were alike, we must look upon them as being, the one on the thigh a direct secondary, and that on the penis a derivative of a secondary lesion in the female received in coitu.

The question of the production of constitutional syphilis from the introduction of a secondary virus, though with the initiatory phenomena of a soft (so-called), non-infecting, or simple sore, is evidenced in these instances. Mr. Wallace has noted at an earlier period the inoculation of condylomata on an infected person. I give his words:—

"T. C., December, 1830.—Condylomata, psoriasis, excoriation of glands, mottled skin, pain in elbow, &c. Was a patient five months previously for gonorrhœa and abscess in perineo. He was inoculated with condylomatous matter in the arm, and produced an ugly ulcer, &c."

He also in 1833 relates the history of three inoculations with condylomatous matter, the second of which so exactly corresponds with one I related in the MEDICAL PRESS of March 8th, 1871, that I have had a *fac simile* of Mr. Wallace's notes lithographed, and interleaved, so that each reader can satisfy himself of the candour and accuracy, of the notator. In these remarks he proves the auto-inoculability of anal condylomata. He proves the inoculability of the same condylomata on "a sound person," producing exactly the appearances of a case I have had lately under treatment, representing the accidental inoculation of a wound on the thumb of a sound male of twenty-seven, followed by constitutional signs, appearing on the fourth day of contact with mucous patches of a syphilitic infant—as shown in the illustration. "*The elevated rim or margin of a whitish-brown colour, spreading to the size of a halfpenny,*" is accurately described in Mr. Wallace's notes in 1833—nearly forty years ago. He shows also the

Primary sore of the thumb, derived from contact with a diseased infant, on a previously healthy subject. Aged twenty-seven.

effect of the same matter on a child in *three days*, without incubation, applied "to the same parts and in the same way" as in the other instances.

ON THE  
QUALITY OF THE WATER-SUPPLY OF SOME  
OF THE LARGE CITIES AND TOWNS OF  
ENGLAND AND SCOTLAND  
IN RELATION TO THEIR SANITARY CONDITION.\*

By H. LETHEBY, M.B., M.A., &c.

IN the course of a rather large professional experience of the quality of the water supplied to the cities and towns of this kingdom, I have had an opportunity of inquiring into the relation of such supply to the public health; and my attention has been especially directed to the comparative value, in a sanitary point of view, of hard and soft waters. The result of these investigations is an unmistakeable advantage in favour of a moderately hard water, such water being not only brighter, cooler, more sparkling, and therefore more agreeable to the eye and to the palate than soft water, but also less likely to absorb organic miasmas, to become charged with living organisms, and to act upon lead and iron than soft water. In addition to which there is strong evidence of the fact that the calcareous matters of such water minister to the physiological wants of the animal system, and protect it from many unwholesome influences.

I intended, at the time when my paper was announced, to have entered very fully into these questions, but the pressure of other professional work, as well as the difficulty of obtaining accurate information of the population and death-rates of the large towns of this country, has compelled me to postpone the subject to a future occasion, when I shall have access to the results of the recent census. It is fortunate, however, that the question of the comparative advantages of hard and soft water has been recently commanding the attention of the people of Edinburgh who are opposed to the corporation scheme for the supply of that city with soft water from St. Mary's Loch, instead of from the Pentlands, the Heriot, and the South Esk, where the water is moderately hard; and the subject has been so ably discussed in a series of letters in the *Scotsman* by a physician (Dr. Wilson, of Edinburgh), that I make no apology for submitting them to you in an abbreviated form, with such comments as my own experience suggests.

In the first place, it is argued that lake water is vapid, mawkish, un aerated as regards carbonic acid, of unstable temperature, and is so prone to be loaded with decaying vegetable and animal organisms as to have been regarded with repugnance in all times. "Frontinus, who was curator of the Roman aqueducts in the first century of our era, when speaking of the now no longer flowing Aqua Alsietina as drawn from the lake of Martignano, wonders how Augustus could determine to bring into Rome 'a water of so little agreeableness and salubrity, and which had never come into popular use and favour,' and accounts for it by his having required it for his shows of mimic sea-fights. And, to leap thence to the close of the seventeenth century, it is in like terms that Fabretti, also a great authority on aqueducts, complains of the deterioration of the original waters of the Trajan aqueduct, through their admixture with those of Lake Bracciano by Pope Paul V.; a combination which still exists as the least prized and used for domestic purposes of the famous aqueducts of Rome."

In more modern time, "the City of Boston, in the United States, is one of the few communities that imprudence has hitherto led, or necessity driven, into the use of a lake water, their supply being from Lake Cochituate, situated at some distance. In a paper published in *Silliman's American Journal of the Sciences* (vol. xix.), Dr. Hayes, the Assayer to the State of Massachusetts, de-

\* Read before the Association of Medical Officers of Health on Saturday, May 20.

scribes the 'numerous animalcules and infusoria, fresh water sponges, and abundance of ochry matter, resulting from the chemical action of the water on the iron pipes,' to be met with in this water. It is only consistent with this, that he finds in it an affinity to 'putrid waters;' and states that 'there are periods in every season, during which it closely approaches to these in character.' In one October, 'the general supply of water had become very offensive.' The water-fleas increased in quantity and in size (from 1-8th to 1-6th of an inch), and 'the cotton filters were soon closed by their bodies;' and in these fleas was detected the chief cause of the offensiveness, consisting in an oily matter in their bodies. The peculiar flavour of the water continued as bad in January as it had been in autumn." In illustration of this I may state that it is no unusual circumstance for living organisms to be so rapidly and abundantly developed in water containing food for their growth, as to become actually offensive. I have known instances of water becoming putrid by the death and decay of such organisms in the main and service pipes of a town. In the case of St. Mary's Loch, according to Dr. Frankland, it was necessary to strain off the fleas from the samples of water before they could be analysed; but as I gather from his published evidence in the case, he only did this "because the process of analysis is so delicate that a couple of these fleas, or three or four of them would have produced a very perceptible difference in the result;" but he thought there was no harm in them, for, to use his own words, he said "he had seen them repeatedly in waters of very good quality. The Manchester water very frequently contains them, delivered in the town, and that is justly considered one of the best waters in the kingdom;" he added that he had drunk it himself for six years; and when he was asked what would be the result of taking these fleas into the human frame, his answer was, "just the same result would follow, I should think, as taking shrimps." The import of all this is, to my mind, very different from that which is contained in the stereotyped phrase of his monthly reports to the Registrar-General, as to the presence of living organisms in the London water, except perhaps that in the one case the creature is rare and microscopic, and in the other abundant and easily seen—of a truth, we may sometimes strain at a gnat, when we can easily swallow a camel. To quote from Mr. Homersham, the civil engineer (*Report of Royal Com., 6286*), concerning the water-supply of Manchester, it would seem that these illustrious strangers, upon whom the municipal authorities have conferred the freedom of the city, are at all times discoverable in the city water. "If," he says, "you take a globular vessel, such as the globes in which gold and silver fish are kept, and which assists in magnifying the insects, you can see them jumping about in all directions." Imagine what would be the state of the public mind in this metropolis if such a condition of things existed. Nor are they alone repulsive to the senses, for occasionally they may be hurtful to the system. An example of this is "adduced by Moleschott, a writer on dietetics of the highest eminence, who states that the frequent diarrhoeas produced by the still-running river waters of the Netherlands, among which he specially mentions the Maas, are commonly attributed to the organisms they contain."

In the second place it is contended that carbonate of lime in water is necessary for the formation of bony tissues. "It is trite to tell, that the bones form the frame-work of the animal structure, without the existence of which, in due hardness and solidity, it could have neither strength, proportion, nor uses. It is almost alike familiar, that more than a half of the substance of the bones, conferring upon them this necessary stability, consists of earthy salts, of which phosphate of lime constitutes the larger portion; the bulk of the remainder, and still a very considerable portion, being carbonate of lime. But it is not a fact so generally or so easily cognoscible, that, according to many proofs and observations advanced, especially by Valentin, a highly distinguished physiologist,

the phosphate of lime itself is frequently first formed within the body, being derived from the lime which has been introduced as carbonate of lime, and which joins itself to phosphoric acid set free from other combinations. In newly formed bones, besides, and in the fresh junctions of fractured bones, he found the relative proportion of the carbonate of lime to the phosphate greatly increased, affording another proof of the essential importance of the existence of the carbonate within the body; while Flettscher and Beneke, in confirmation, have remarked the more rapid union of fractures under its use. Analogous observations have been made by Seegen. By an opposite set of proofs, Boussingault, Chossat, and Seegen have shown the injury to the solidity of the bones, in instances where carbonate of lime has been incidentally or designedly withheld. In the disease of rickets in children also, a well-known scourge in dense populations, there is an interruption in the process of ossification, the proportion of earthy salts in the bones being sometimes reduced by two-thirds; and it must here be manifest how much further damage may be effected in increasing the number, or in aggravating the affliction, of the puny and distorted victims of the disease, by an arbitrary abstraction of the supply of the carbonate of lime provided by nature. Scrofulous diseases, moreover, so wide in their range, and so destructive in their direct as well as indirect influence, owe much to the moderate and habitual use of lime for their prevention, as at one time, before the discovery of iodine, they depended extensively upon it for their cure. Taken from our drinking-waters, besides, lime takes along with it their freshness and sapidity, and leaves them destitute of a stimulus to the stomach and its functions more truly efficient, and in the end more wholesome than the most relished of condiments. And it is precisely through our best, and in all ages most esteemed, class of drinking-waters that this salutary agent is, though existing in other articles of aliment, presented to us the most regularly, the most habitually, under the most varied forms of diet, and in that state of solution the most adapted for its reception and assimilation within the system. But even if water could be proved to afford only the half of our supply of this wholesome agency, necessary and advantageous at all times, and in the periods of growth a special mainstay; and if reckless or sanguine minds were bold enough to assume, what, to say the least, has never yet, either in proper extent, or adequate duration of time, been anywhere even duly tested, and were to maintain that the part to be procured from other sources was sufficient for all our wants, would it be wise in us, on such grounds, so laxly established, to reject the half of the wealth offered us by nature, that we might make the experiment of subsisting on the remainder." I have elsewhere observed, in my published lectures "On Food," that four-fifths of the earth's surface are composed of calcareous strata, which yield water that is more or less rich in carbonate and sulphate of lime; and it may be that this is a wise provision for the supply of these salts to the animal system. As the late Mr. Johnson truly observed, in his "Chemistry of Common Life," "the bright sparkling hard waters which gush out in frequent springs from our chalk and other limestone rocks are relished to drink, not merely because they are grateful to the eye, but because there is something exhilarating in the excess of carbonic acid they contain and give off as they pass through the warm mouth and throat; and because the lime they hold in solution removes acid matters from the stomach, and thus acts as a grateful medicine to the system. To abandon the use of such a water, and to drink daily in its stead one entirely free from mineral matter, so far from improving the health, may injure it;" in fact, the water of a country may determine the diet of its inhabitants. The soft waters of the lakes of Scotland, for example, may have had something to do with the choice of brown meal; and but for the calcareous waters of Ireland, the potato could not have become a national food. "The criterion, therefore, of the wholesomeness of a

water, depends, not merely on facts and observations of scientific exactness, but on the demonstration of a general sense of fitness and probability which has attracted to it the spontaneous assent of the world in all ages, with a degree of unanimity that has remained unbroken till very recent times, and even yet in singularly few examples. Of the higher kind of assent, that of physicians and chemists of eminence, including those who have made the subject of the preservation of health a peculiar study, I could offer almost countless further instances; and proceed to add a few, selecting from among only the more recent, and naming none unless of high merit and distinction, as well as of special authority on the question. Johnston, speaking in his 'Agricultural Chemistry' of the presence of earthy salts in water, says that 'it is not without a purpose that all water we meet with is thus impure. The fluids of the animal body contain nearly the same saline substances as are present in the water we drink, and from this source it is no doubt intended that a certain portion of those saline substances should be obtained upon which the preservation and health of our bodies depend.' 'Thus there is an obvious design and adaptation in the impurity of our spring and river waters, for by that impurity they are better fitted to minister to the wants of living beings.' (The italics are in the original.) 'We see,' remarks Bousisingault, in his 'Memoirs on Agricultural Chemistry and Physiology,' 'by what precedes, that the saline substances dissolved in water have their place in alimentation, which, without their assistance, would have been insufficient.' Dupasquier points out the usefulness of bicarbonate of lime in potable water; urging that 'the quality of potable waters stands in no relation with their degree of purity; that the purest waters, with regard to the quantity of matters dissolved, are not on that account the best; and that it is by a truly providential provision of nature that waters contain more or less of foreign matters in solution.' Riche, Professor at the School of Pharmacy at Paris, says, in a recent lecture, that spring water is the best of all waters; and for this he adds to his own authority that of the eminent chemist, Dumas. He notifies further that carbonate of lime, if in small proportion, gives an agreeable taste, and is salubrious; and that it is by carbonic acid that the lime necessary for our organism is dissolved, by which water is converted into a veritable aliment. Tardieu, the great authority on public health in France, states that most writers hold the presence of one part of carbonate of lime in two thousand of water as advantageous. Oesterlen, who is to Germany, in many respects, what Tardieu is to France, says that a chemically pure water is by no means the pleasantest water to drink; that the sparkling clearness, and agreeable and refreshing qualities to be desired, depend much on moderate impregnation with salts of lime; and that these salts of lime, so presented to us, are required for our bones and other tissues. In a report made to the Academy of Medicine in Paris, by MM. Poggiale, Boudet, and Tardieu, and adopted by that distinguished body, it is remarked that all communities seek spring water, even at great sacrifices of cost; and, among others, nine principal places of France are specified, with some foreign examples, as Rome, Brussels and Edinburgh. They point out as an error to be combated, that the chemically purest waters are the best; the saline matters being necessary to the support of life, becoming absorbed like alimentary substances, forming thus part of our organisation, and requiring renewal like its other portions. Lefort considers that a drinking water should contain enough of mineral salts to contribute to the process of ossification; and he has the further statement, that a water which holds dissolved the greatest possible proportion of carbonic acid, oxygen, and nitrogen, and which contains carbonate of lime in quantity below that which curdles soap, leaves nothing to be desired, whether for drinking or for household economy. Professor Bouchardat recognises the usefulness of carbonate of lime in waters for a variety of services to the living system, and amongst these for aiding the nutrition of the young, by supplying an indispensable aliment to the bones; and it

is on this ground that he considers rain-water too pure, the absence of the salts of lime being prejudicial to 'nurses, children in early life, and young animals.' Hugueny sets the chief value on the existence of lime in waters, from its being required in the period of man's growth; and Agassiz, to possess whom amongst them is a pride to the Americans, has remarked that the drinking of water in limestone regions enlarges the skeleton. And let it be remembered, as another important element for consideration in the choice of a drinking water, that it has been found that the original temperature of a source becomes little affected by transmission through even covered conduits. Many observations of this have been made abroad; and, among others, by MM. Commaille and Lambert at Rome, who have ascertained that the waters from springs, which supply that city so profusely, are uniformly fresh and cool in summer as in winter; while the water brought to supply a fountain from the lakes Bracciano and Martignano, though it arrives in such mass as to drive mills, is variable in temperature, warm in summer and cold in winter. Thus the *agua virgo*, esteemed the best in Rome, arising from springs, and flowing under ground in an ancient conduit, was found to show a heat of 57 degs. F.; while the more modern supply from the lakes, introduced in the seventeenth century by Pope Paul V., and flowing also through a subterranean conduit, both being of considerable length, stood as high as 73 degs. F., the temperature of the air at the hour of the experiment being about a degree lower. In a word, it was unfit to refresh or quench thirst. If the authorities here quoted are chiefly foreign, it is because the subject has been infinitely more and better considered in foreign countries than in our own."

"But it may be asked whether all the authorities are thus on one side, and whether there be no conflicting testimony to adduce, and which assuredly ought not to be concealed. It is merely the truth, however, to state that such testimony occurs only with extreme rarity, is presented by far less eminent authorities, and occurs with an incompleteness, and often with an inaccuracy, that tallies with the difficulties that were to be encountered where the probabilities it had to contend against were so strong and so manifold. 'Thus,' says the physician, 'I have seen it stated that the Dutch drink waters destitute of carbonate of lime, and yet are a healthy and robust people. But my knowledge of Dutch Medical literature is neither so indirect nor so scanty as not to have made me aware how far such a statement is from being supported by the facts. A journal, under the leading editorship of the singularly able Professor Donders, of Utrecht, speaks of the 'duinwater,' with which Amsterdam is chiefly supplied, as containing more than double the quantity of carbonate of lime (no less than 1½ grains to the gallon) than is dissolved in the 'schuifwater,' a source of supply which has been partially introduced; and assigns this as one of the qualities which confer upon the former a decided superiority as a drinking water. A writer in another Dutch Medical journal speaks of a well at Amsterdam, the water of which contains even a larger proportion of carbonate of lime, on the score of which he claims for it a decided preference over rain and river water; and he remarks that no instructed person can dispute the great value of a certain proportion of this substance in drinking waters, for the uses of the organisation. In a paper read before the Academy of Sciences at Amsterdam, the wells at Utrecht, The Hague, Middelburg, Leyden, Zwolle, and Bois-le-duc, are severally instanced as containing very considerable portions of carbonate of lime. And so this alleged fact falls to the ground. Another instance which has been cited is that of Aberdeen. But who shall say, after the facts and opinions which will be adduced, that there is no relation between the inferior quality of the water at Aberdeen, and the appreciably higher mortality there than in Edinburgh, as shown, in the mean of ten years terminating in 1866, by the returns of the Registrar-General—Aberdeen having a far less numerous and less dense population." Referring to the evidence of Dr. Angus Smith

(Report of Royal Commission, 7,261) that in his opinion the tallest people in Great Britain are to be met with in soft water districts, for instance, in Cumberland, and probably in Aberdeen, the physician says "that as this is evidently only a surmise, derived from no actual investigation, he might be content to meet it with a retort founded at least upon something better than surmise." "It has," he says, "always been impressed on me as a fact, which has been confirmed to me by a late friend and patient, who was for long surgeon to the Life Guards, and still more recently by an intelligent non-commissioned officer, retired from the same body, that its best and tallest recruits, or, in other words, the finest men in the realm, were obtained from the border districts of England and Scotland, descending southwards through a considerable part of Yorkshire. But fortunately, there is no need of making this altogether a matter of surmise, or of conjecture on imperfect evidence, in any form. Every district may not be imbued with equal military ardour, nor may it always be a safe criterion to judge of the mass of a population from a gleaning of its more remarkable examples. It is only possible to arrive at a proper estimate by taking promiscuously the population as it presents itself; and this has been recently done in a wide series of measurements, taken in all parts of the country, by Dr. Beddoe, with the aid of many coadjutors, and recorded by him in the last published volume of the Memoirs of the Anthropological Society, making us indebted to him for by far the completest and most authentic document of the kind that has been hitherto published. From it we learn that, in Scotland, the Borderers in general (p. 542) equal or surpass the average of the country both in height and weight; while the Borderers of the English side have a still more unequivocal superiority over their own countrymen. These men live, not on the granite or gneiss, nor the slates, giving origin to soft water, but over the lime of the coal formation, with the shales and marls and magnesian limestones of the sandstone formations; and the waters they drink are hard, those of Berwickshire and Roxburghshire thickly incrusting the housewives' kettles. Over the abundant limestones of Yorkshire, the men are among the tallest in England; and Dr. Beddoe specially instances, here the inhabitants around Richmond and in Swaledale. The average for Berwickshire is actually an inch and a-half above that of Aberdeen; while, as to Cumberland, Dr. Beddoe gives to it, excluding Carlisle, an average of an inch below Berwickshire, and half-an-inch above Aberdeen. This result seems naturally explained, if we consider that the level parts of that county are of the new red sandstone formation, or the coal formation, and that a broad belt of limestone surrounds the mass of slaty hills in the interior, so that the greater portion of the population lives beyond the soft-water limits. 'In the old red sandstone district,' says Professor Ramsay, in his Lectures on Physical Geology, 'where the marls are somewhat calcareous and interstratified with impure concretionary limestone, called crystone, the waters are hard. Again, the waters which flow from the Pennine chain, that extends from the southern borders of Scotland into Northumberland, are all hard, because they drain areas composed chiefly of the carboniferous limestone; and all the rivers that run east from this range, over the new red sandstone and lias, and the oolitic and cretaceous rocks, are of necessity exceedingly hard.' And such waters supply the homes of those shown by Dr. Beddoe to be the generally most stately and vigorous of our population. Thus Dr. Smith's statements, relied on by Dr. Frankland, appear only as the product of vague impressions, reached without special inquiry, and hazarded without comparison or consideration; and such have ever intruded themselves into science as its opprobrium, compelling it rather to engage itself with the wearying task of the extirpation of error than with the cheerful labour of the discovery and establishment of truth. But Dr. Smith makes yet another statement, which Dr. Frankland

does not quote, in the form of an assertion that the smallest number of deaths occurs in the western district of Scotland, where there is soft water; and which I now introduce here in order to controvert it also. Let us select two typical counties, Argyleshire and Berwickshire, each with thirty-one parishes; and we find from the returns of the Registrar-General that, on an average of the ten years ending in 1864, while Argyleshire had only eleven parishes with a mortality smaller than fifteen in the thousand, Berwickshire had as many as nineteen, the two lowest rates in the former being 11'4 and 12'8, but in the latter only 5'6 and 7'4. Roxburghshire, too, out of the like number of parishes, shows the same proportion of nineteen which have a death-rate under 15 per thousand."

"What is true of man, in this country, in relation to the connection between his vigour of growth and the existence of carbonate of lime in his drinking water, is true of him also in other countries, and is not less true with regard to the lower animals. To content ourselves with the most remarkable of all examples, we may refer to the Patagonian savages, still universally acknowledged, after the removal of somewhat of former exaggeration, to be the most gigantic race known, whose home is on the tertiary plains of their country; while their immediate neighbours to the west, living among the extreme hills of the range of the Andes, are of far less stature, but still greater savages. Reference has already been made to the testimony of Agassiz on this point of stature, as well as to the conclusions regarding it arrived at by the Ministerial Commissions of France and Austria. M. Durand de Gros, quoted by Dr. Beddoe, has lately, in an important paper on the influence of mediums in the Aveyron, claimed a higher stature for the natives, human as well as bovine, of the calcareous districts in that department. As to cattle in this country, it will be remembered that all our finest breeds have originated in the hard-water tracts of the shires of Lincoln, Leicester, York, Durham, and Northumberland; and that these breeds have been everywhere largely used to improve the races in other districts, and must still be frequently reverted to by the latter for the maintenance of what are only acquired, rather than inherent, excellences. The same may be said of our sheep, all our best flocks being indebted for many of their highest qualities to the breed of Leicesters, reared on the lias, with its marl and limestones, and the sandstones of their native county. And so again of our horses, whose best and stateliest forms are developed among the carboniferous limestones of Lower Clydesdale, of Northumberland, and of Yorkshire, or, if we look abroad, upon the tertiary strata of Holstein and Flanders; while among the gneiss of Shetland and the Grampians, and the slates of Wales and Cumberland, we have the diminutive Welsh and Highland sheep and the Herdwicks, the kylo, and the pony, as the characteristic indigenous races."

And now to another point:—

"The epithet of purity, with regard to water, is one that has been grossly misapplied. Apart from chemistry, and with reference to its salubrious uses, a water is no more entitled to be termed pure because it is destitute of a moderate impregnation of earthy salts, than a beer is pure in the proportion that it is little imbued with the extract of malt, or a soup with animal juices. Its purity consists in its commensurate endowment with those properties that fit it for promoting the growth, and sustaining the functions, of the living system. Were our aims for a community to be lowered from the consideration of how we might raise to the highest perfection its health and its vigour, and so conduce to its happiness and well-being, to that of how we best might aid it in economising its soap, then the application of the term purity to a water unimpregnated with earthy salts would conceal under it less of a mischievous fallacy. But, even here, what is wholly true, in a chemical sense, of the effect of the hardness of water in decomposing soap, is only partially true in a practical application." "Where neither the observing nor the logical faculty has ever necessarily

been specially or habitually exercised, men's minds see only that which lies most prominently before them, and, deciding upon it, ignore the rest, because it does not lie within the sphere of their inquiry, and because of the difficulty they have in penetrating to the principal quality when it is not the most apparent. Thus on purity, in this matter, as bearing on soap, they have a glimmer of light: but on purity, as affecting the laws of life and organisation, which they have made no object of study, they are absolutely in the dark."

The Royal Commissioners, in their report on water supply, have made a special reference to the misapplication and abuse of the term impurity as applied to the solid constituents of water; for they say we cannot "agree with some eminent authorities in looking at river water solely from a chemical point of view, and speaking of the presence of the 10 or 20 grains of mineral matter in a gallon of water as *impurities*. So, chemically speaking, they are, but as this seems to be almost a normal condition of river waters, we should not be disposed to consider this term an appropriate one to be applied to substances so constantly present in natural springs and streams. And further, we cannot but consider it unphilosophical when, in addition to treating as '*impurities*' substances perfectly harmless even in much larger quantities, the minute quantities present in a gallon, or any other small measure of water, are multiplied by taking masses of water, such as the individual never has to deal with, and given to the public in figures so large as to tend to cause misconception, and perhaps unnecessary alarm in the minds of those not conversant with all the conditions of the case. It would be as just to speak of the small proportion of carbonic acid present in the atmosphere, equally in populous cities, and in the Alps, as an impurity, and to startle those unacquainted with the subject by giving in some large figures the total quantity of that gas present in the atmosphere of London." (p. xciii.)

As you are aware, the conclusion of the Royal Commission on Water Supply was that hard water, like that of the Thames, is preferable to soft for the supply of London; and a like opinion in respect of Paris and Vienna was arrived at by the savans appointed to investigate the subject of the water supply to those cities. But in reply to this, says the physician, "Dr. Frankland adventures the statement that, 'in respect of that section of sanitary science which is devoted to town drainage and water supply, our Continental brethren are at least a quarter of a century behind us.' This was said with the evident intention of depreciating a part of the eminent authorities already quoted: and yet what is it but merely a repetition of the old fallacy, that asserts what is the truth of one thing which has not been denied, and is not even in question, in order to have it accepted, by minds little practised in logic, as true of another thing which is denied, and is the real matter at issue? It is this setting of a partial and non-essential truth, in the place of the main and vital truth, that most easily misleads the undisciplined reasoner, and thus forms the pest of controversy. No one has disputed that, in the actual practical details of what may be termed municipal and domestic hydraulics, in as far as the mere distribution of water is concerned, the mechanism employed by us, as well in extent as in quality, is generally superior, not to what is known among men of science, but to what has been commonly adopted among the habits of life of the Continent. But, for anything beyond this, to assume a superiority for this country seems to me the most unwarranted of pretences. When we turn to the whole broad science of hydrology, having for its object the study of the qualities of water, whether fresh or sea, pure or mineralised, including the nature and variety of its constituents, with their physiological and sanatory, as well as sanitary, properties and actions, while our own home literature is either an utter void, or shows little beyond a few treatises of neither repute nor originality, we find that of the Continent rich

with an array of special and general disquisitions; and these proceeding for the most part from men who, with the basis of an ordinary medical education, have received a direct appointment from Government to superintend and officiate at the various watering places, and who have thus been constrained to make the subject of water, with its actions on the human frame, and those of its various modes of impregnation, the peculiar study of their lives. Let any one refer to a work so well known among the better educated of medical men as Plouquet's "Digest of Medical Literature," and let him run his eye down the long columns containing the catalogue of dissertations on the topic of water, in all its forms and varieties, published up to a little beyond the close of the last century, and he will soon discern how very minute is the proportion among these of the works of British authors. Nor has this proportion changed since. We have no names to place in rivalry, just or unjust, with those of Osann, Helfft, Simon, Fwih, Vetter, James, Posner, Seegen, Durand-Fardel, Lersch, Graefe, Kalisch, Spengler, and many others, besides those I have formerly quoted, all very recent or still living authors."

"Doubtless there have been fluctuations of opinion; for a credulity that believes anything, and a scepticism that tests everything, have been ever the bane and the antidote in scientific progress, the fate of which is still to advance among the ruins of temporary reputations: though the actual state of our knowledge, on this topic of water, is best evinced by the recent decisions of the Government Commissions of the three chief centres of European civilisation, who have obviously possessed, and have fully used, the best means of gathering proofs and eliciting or eliminating opinions. It is besides characteristic of the zeal with which the study of this subject is pursued abroad, that there are at least four periodicals specially devoted there to its investigation, while in this country it would be a futile attempt to produce one."

But the most remarkable fact for consideration is the comparatively high mortality in towns supplied with soft water, the mortality being almost in the direct proportion of softness. This has been ably discussed by the physician who says:—

"In the appendix to the report of the Royal Commission, there is to be found (p. 77) a table, presented by Drs. Letheby and Odling, and Professor Abel, from which much weighty instruction is to be derived. Its design is to show the relation between the quality of water, more especially as to its degrees of hardness per gallon, and the prevalent rates of mortality in twenty-seven cities and towns, twenty-four of which are in England, and three in Scotland. But as the towns are grouped in only two divisions, according as the waters are above or below 10 degrees of hardness, and as the mortality seems to be founded on that of only a single year, I have thought it better, for the sake of greater security, to re-cast, and add to, the materials, founding the rates of mortality, with a very few casual exceptions, on averages of ten years, while increasing by thirty-eight the number of the towns and cities, five of them being in Scotland. The sixty-five towns thus collated, I now place under four several categories as to their degrees of hardness: the first group embracing those above 10 degrees, the second those of from 10 to 6 degrees, the third those of from 6 to 2 degrees, and the fourth those of 2 degrees and under. Within the first group are embraced twenty-five towns, among which is London; their average population being above 230,000, and the mean hardness of the waters 16.0 degrees per gallon. In the second group seventeen towns are included, having an average population of above 137,000, and an average hardness of 8.0 degrees per gallon. In the third group there are fifteen towns, the average population being above 120,000, and the hardness 3.8 degrees; while in the fourth group the towns are eight in number, the average population amounting to above 88,000, and the hardness to 1.3 degrees per gallon. In all

statistical inquiries, we know that we approach the nearer the truth the more carefully arranged are our categories, and the more widely they are based on extent of numbers and time; and we have here enough to reach a tolerably safe approximation. The facts elicited are striking and important."

(To be continued.)

## NOTES OF A CASE OF SYPHILITIC HERPES WHICH AT FIRST RESEMBLED SMALL-POX.

By WM. CURRAN, Army Medical Staff.

At a season like the present, when small-pox prevails epidemically and is numbering its victims by the hundred, whatever tends to mitigate its horrors, or divest them of their hideous repulsiveness, is worthy of attention. In this light eruptions that resemble its manifestations, and yet are of a very different character and complexion, deserve special notice, inasmuch as an early appreciation of their differences may serve to save much suffering to the patient and anxiety to his friends, and enhance at the same time the professional repute of his attendant. The case recorded below is an instance in point. It occurred in the person of a young man in whom the marks of vaccination were not very pronounced, in a hospital in which small-pox had been previously treated, and under other circumstances of time, locality, and accession, which warranted doubt, if they did not actually suggest danger. Though the former exists no longer and that all apprehension of the latter has long since ceased, yet is the case no less interesting from a diagnostic point of view, and there are, perhaps fortunately, but few opportunities of contrasting the rarer manifestations of syphilis with those of small-pox. For these reasons, if for no other, the case calls for notice. It is based on notes taken by myself at the bedside, and I am anxious to contribute, by its aid, to the formation of a more accurate diagnosis than I arrived at, or than is always attainable in similar instances. The attainment of this would alone justify its publication, but it possesses other features of interest, which if not peculiar to itself, are yet so rare as to warrant their reproduction here, and for the rest the particulars given below must speak for themselves.

No. 1272, Private J. H., of the — Lancers, nineteen years of age, who has not yet completed two years' service, says that he had a sore on the prepuce three years ago, which would appear, from his own account of it, to have been a soft one, and which he adds healed of itself, under his own management, and with such aid only as he could derive from rest and the application of cold water. This does not appear to have affected him constitutionally, either then or subsequently. He now possesses the average vigour of a man of his age, and he says himself he always enjoyed good health. He confesses to having had frequent intercourse with loose women since. He was, indeed, about this time, very indiscriminating in the exercise of his attentions to them, and he was treated for gonorrhœa in his own regimental hospital six or seven months ago. He distinctly denies having had any other venereal disease, and he claims some merit for having refrained altogether from cohabitation for several months after his last attack. He adds that it had also the effect of rendering him much more cautious than he used to be in the selection of his favourites, and it would appear from his statements in the matter—if they are reliable—that he exercised, up to a recent period, a degree of caution and reserve in the practice of his loose amours which are not common in soldiers of his age. Nevertheless, he seems to have indulged in frequent coitus, and he is now quite unable to point to any one intercourse or woman as the source of his present ailment.

On admission to hospital, on the 16th March last, he was

found to be suffering from a hard sore of some five days' duration on the under aspect of the prepuce, and that structure was itself enlarged, swollen, and pendulous. The glans looked red and irritable, and there was some reduced and infiltration of the neighbouring integument. He says his present sore occupies the very same position as that occupied by his former one, and it appeared eight days after connection. The glands in both groins were enlarged and indurated, the nuchal glands were also enlarged, but there was no tenderness in either, and he could bear pressure on them all without flinching. He was placed in one of the wards appropriated to the accommodation of such cases, the sore was dressed in the ordinary way, and mercury was not exhibited. On the evening of the 21st of same month a papula-roseoloid eruption appeared on the arms and trunk, and this soon passed through the usual stages of papule, vesicle, and pustule. It spread rapidly under the form of zones, with a broad base and dusky discolouration over the abdomen and round the loins, and thence upwards and downwards to invade the face and the extremities. Within thirty-six hours it had made its way to most parts of the body, and meanwhile there was no thirst or heat of skin, no pain in the loins or feeling of constriction about the temples, nothing, in fact, to denote the approach, or indicate the recession of fever. He ate and slept well, was evidently free from pain, and he seemed somewhat surprised at the attention his condition was receiving.

The face was attacked on or about the 24th, and was quite covered over the alæ of the nose and under the eyes on the 28th or thereabouts, but the eruption did not here assume so markedly vesicular a form as elsewhere, and the scabbing and discolouration were also less. Meanwhile the eruption on the belly began to fade, but as it faded from the abdomen it appeared on the thighs and calves of the legs, and it bore everywhere, and from the very first, a striking resemblance to an attack of modified small-pox. There were, however, none of the usual accessories of that disorder, the eruption in the case under review did not follow the same sequence, and its course and continuance evidently entitle it to a separate designation and character. Altogether the eruption lasted about eight days or so on the chest and abdomen, and it has already taken upwards of three weeks to exhaust itself elsewhere. Indeed, it can scarcely be said to have run its course in that time as new vesicles continue to appear in various parts of the body, and I counted myself towards the middle of April a fresh crop just above the right knee and over instep of left leg. Though his health has not suffered much, he yet appeared to be weakened by the discharge, and he was allowed support accordingly from an early period.

As regards the character of the eruption the vesicles were of about the usual size of varioloid, but there was no appearance of mammillation about them anywhere, and each contained a hair in its centre, which would seem to imply that the follicles were more engaged than the cutis itself. They also had a broader base and a more globular form than those of small-pox, the contents at first limpid and transparent soon became opaque, of a citron hue, and there was no escape of fluid from them at any time. The process of scabbing was brought about not so much by maturation as by the development of a little dark spot in the centre of each, which, increasing in area, as it receded from the centre, gradually extended to the side, and finally involved the whole surface. The liquid contents underwent, meanwhile, a process of solidification or concretion, which displaced, as it were, the overlying crust, and then disclosed a discoloured and slightly indented surface underneath. The treatment consisted in confinement to bed in a roomy, well-ventilated, and separate ward, in attention to the bowels, and the use of sufficiently supporting stimulant diet. Nevertheless, fresh crops continued to appear, patches of eczema complicated their presence on the legs, iritis aggravated his sufferings, and subsequently he will have reason to congratulate

himself if he escapes the effects of a progressive syphilitic cachexia.

*Remarks.*—Such interest as may be supposed to attach to the recital of this case centres in the fact that it was, at first, mistaken by myself and a junior colleague for small-pox, and that, too, in the face of the doubts expressed by the surgeon-major in charge, and the more decided stand taken on the other side by my friend, Staff-Surgeon Dr. J. Johnson, to whose aid and guidance I am indebted for the reference given below, as well as for later information regarding it. We are both now satisfied that we were wrong, and on looking into the literature of the subject, I find that the disease, though a rare one, is yet of more frequent occurrence than I had anticipated. There is, as far as I can make out, little or no mention made of it in the older syphilographers, but it is well portrayed in the works of Cazenave, Bumstead, and Lancereaux, and a few sentences from each of these will throw more light on its history and progress than any description I could hope to indite. Cazenave—translated by Burgess—p. 371, describing the disease under the head of *Vesicular Syphilitic Eruption*, says:—"This variety was for a long time considered as one of the most rare forms which syphilis could assume. Bielt met with it only a few times, but we have seen it repeatedly, and believe that, if not very common, it occurs more frequently than is generally supposed." And after giving some particulars of the case of a girl, sixteen years of age, on whose body a number of small eminences appeared, "after she had complained of some sense of heat in the throat, difficulty in swallowing, anorexia, and irregular fever," he adds, "the eruption was at once seen to be vesicular and pronounced chicken-pox. . . . It covered nearly the whole body, and the vesicles were in different stages, some being nascent and others dried up. . . ." The vesicles were small, resting on a broad base, and surrounded by an areola of vivid copper colour, their progress was slow, and they were unattended by any local symptoms. They gradually faded away and the fluid was absorbed, but in some the contents of the vesicle, hardened into a thin scab, every one of them left behind a coppery infection of the skin, which presented all the characters of a syphilitic blotch." The underlining is mine, but the point of the description can be easily realised without it, and the great syphilographer, Bumstead, is even more precise and circumstantial. He says, under the head of "syphilitic vesicles," p. 547, "a vesicular eruption is the rarest of all the syphylodermata, although it is now admitted to be more frequent than was at one time supposed. . . . The parts, which are most frequently affected, are the back, face, and extremities. The vesicles may be either large and globular, small and acuminated, scattered irregularly over the surface, or arranged in groups. Many of them are found to be traversed by a hair, showing that the chief seat of the eruption is the hair follicle." He elsewhere describes them as "containing a citrine coloured fluid, and arranged in irregular groups seated upon a dark red base," or, "the vesicles may be smaller and collected into groups, which are either circular or ovoid, as in herpes circinatus." This is exactly the shape, or rather shapes assumed by the eruption here referred to, and Lancereaux describing the same disease from his stand-point, says: "*La syphilide vesiculeuse à forme de varicella, dans laquelle les vesicules disseminées, tantôt acuminées, tantôt globuleuses et quelquefois ombilicées, sont remplies d'une sérosité qui se trouble rapidement et finit souvent par se changer en un liquide purulent: d'ovale ressemblance plus grande avec la varioloïde qu'avec la varicella.*" Andagaiso, p. 143, "*La syphilide vésiculeuse à forme d'herpes offre des vésicules disposées en groupes irréguliers, ayant l'aspect de l'herpes phyléténoïde, ou bien en groupes arrosidés ou ovales affectant la forme circinée.*" These few quotations from such accessible sources clearly prove the existence of a disease which may, at its first appearance, and

especially so, at seasons like the present, be easily mistaken for small-pox, and the mistake is much more likely to happen in a hospital, in which the last named disease already existed.

The absence of premonitory symptoms, the sudden accession of the rash, the comparative immunity of the face, and the character, and the progress of the attack ought, indeed, to have put me on my guard, but I had never seen a similar case before, and as Carmichael well observes, "all eruptions, venereal or not venereal, imperceptibly glide into those of the nearest character, and it often happens that practitioners can only determine the nature of the eruptions, for which he (*sic*) is called upon to prescribe by an attentive consideration of its progress." The true nature of this case only developed itself as in advanced, it is, therefore, calculated to inspire caution and counsel reserve, and its record may prove useful to others, by showing that such a condition occasionally obtains, and clearing the course for a more accurate appreciation and diagnosis of eruptive diseases. As such it is offered for publication here in the hope that the perusal of its history, however imperfectly executed, may induce others to suspend their judgment, and wait for appearances which can only be determined by time, and which even the most experienced may sometimes misinterpret or mistake. Injudicious interference or erroneous pronouncement must necessarily be the consequence of an opposite course, both these are to be avoided as calculated to create alarm and inspire distrust, and the resources of our art are weak enough already without having their weakness more blazoned forth, and mayhap exaggerated by precipitate action, or too evident straining after effect. This is the lesson the case is intended to teach, and if it only teach this well, it will have more than realised the object I had in view in drawing it up.

#### FURTHER HINTS HOW TO MAKE VACCINATION MORE EFFICACIOUS.

BY ROBERT HANSLIP SERS, M.R.C.S.E.

It would be tedious, and indeed uncalled for, to offer many cases in detail to prove the necessity of a sufficient protection for the recently vaccinated arm. Four examples now to be seen in my practice may serve to illustrate this important point.

CASE 1.—J. W., æt. twenty-two, unmarried, residing at a neighbouring village, always enjoyed good health, yet of delicate frame of body. His father died from a second attack of carbuncle, and his mother is subject to a yearly "breaking out," patient had not been vaccinated, and was now "done," because he had entered Her Majesty's service as a letter carrier. I vaccinated him from lymph a week old, preserved in a capillary tubo (one tube out of twelve, all the lymph obtainable by selection from twenty-four children). Vesicle on the eighth day perfect; commencing areola slight. On the nineteenth day after the operation, besides attending to his usual duties, he mowed a grass plat, two hours' work. The arm in the evening of this day commenced to swell. No glandular enlargements in the axilla. Subsequently a series of six boils appeared on the arm and forearm. In spite of two days' fever and slight disturbance of sleep—his appetite was better than usual, and with the above exceptions he did not "feel ill." The scabs falling off, the vaccinated points at about the twenty-first day revealed the characteristic cicatrices. This was evidently a purely local affection produced by direct irritation. Fortunately the patient was in good health at the time, or the consequences might have been serious.

CASE 2.—An infant living in my village. On the fifth

day, one of the vesicles completely rubbed away. It is to be observed that the vesicles at this point are easily injured.

CASE 3.—An infant in an adjoining village. Well formed vesicles on the eighth day, but covered with the accumulated dust of the week—one of the vesicles in particular was obscured through commencing irritation produced by mingled dust, grit and hair. A suitable habitation “germs proper,” to say nothing of “germs theoretical.”

CASE 4.—The child of R. M., æt. six months, living at Cay Thorpe, vesicles on eighth day in apparently good condition; areola inclined to be erythematous; the vesicles had been ruptured. I mention this last case, because I consider that vesicles frequently burst, *keep discharging and refilling*, and that the *subsequent virus* loses its virtue, and may even *become inert*.

When the forearm cannot be easily flexed, as with soldiers and policeman, the discomfort of vaccination and the risk of undue inflammatory action must be increased. With infants and children the sleeves can be looped up, but this often fails in its object. I firmly believe that the perfect removal of these sources of danger is absolutely necessary to the development of complete vaccination. With the assistance of Mr. Miller, of Leicester square, London, I hope shortly to obtain a good vaccination sleeve, made of polished leather and perforated zinc—points of fixture, neck and dress of child. A full description of this sleeve, with an illustration thereof, should it answer its purpose, shall be given on a future occasion. The special advantages supposed to be gained by this contrivance are increased safety, cleanliness, comfort, and a fuller supply of powerful lymph. It is surprising how rarely arm to arm vaccination fails, when we consider that many escape a contagious and infectious disease, although fully exposed to it.

Vaccination performed from preserved lymph may be termed a modified vaccinia, it has not the same vigour—the vesicles are not so plump, it is doubtless less effective as regards immediate good and permanent result. I have just looked at an arm lately vaccinated with virus from London. The child's mother tells me that it took well, and that the doctor requested to take a supply of lymph therefrom, only small spots are visible with a single indentation to each. In the course of a few years, the cicatrix failing to grow, must be almost obliterated. If the vaccine vesicle has run its due course, the scab fallen away at the right time, the cicatrix, a proper one (“circular, somewhat depressed, dotted or indented with minute pits, and in some instances radiated”); we may safely give a certificate of successful vaccination. Nevertheless the child may afterwards present symptoms of an acquired disease. The burden of the proof must then fall upon the opposing party, he must prove that the vacciner had one or other of these dire diseases, and that the child vaccinated was together with its progenitors perfectly free from disease. A truly difficult task.

The eruptions of childhood are to be looked for. Only a few weeks ago I was at the point of vaccinating a baby with a very clear skin. Fortunately I had forgotten my vaccination case, for three days after the child was covered with a squamous coppery coloured eruption. It is a truism to say that the fevers produced by vaccinia may hasten the appearance of skin eruptions. In instructions for vaccination under contract, we are told (Gregory revised by Ceely and Marson) “on the ninth or tenth day, especially if the weather be hot, children of full habit not infrequently show on the extremities, and less copiously in the trunk, a lichenous, roscolar, or vesicular eruption which commonly continues for about a week.” Unquestionably in the greater number of cases, vaccination merely *forwards* these eruptions, it does not *create* them. Children are frequently brought to be vaccinated with a rash too slight to forbid the operation. One would not heed slight pityriasis of the scalp so common among chil-

dren. Impetigo of the scalp is rare in my districts, therefore I should not expect it to be coincident with the vaccinia. It is generally known that the skin and bowels often sympathise. I have thought that vaccination has sometimes failed from the setting in of a coincident diarrhoea. But I should not attribute the diarrhoea to imperfect vaccination, or impure or effete matter. Need I say that the appearance of healthy looking rashes require no such explanation. The purest lymph may fail to take altogether; or it may produce a papula, or a minute vesicle, or a pustule, according to attendant circumstances. Contagious diseases are more likely to be *given* in the ordinary way, than to be *contained* in lymph taken and used with common care.

I now arrive at a point of great importance—viz., the health of the vacciner, clean lancets—perhaps one for taking virus; another for vaccinating; the avoidance of the least stain of blood; these are easy of attainment, but to feel convinced that the vacciner is healthy, and the child to be vaccinated also healthy, here are problems, the solution of which the instructions to vaccinate under contract do but little to elucidate. We may “satisfy our selves that there is not any eruptions behind the ears or elsewhere on the skin, nor any febrile state, nor any irritation of the bowels,” we may “take matter from an apparently healthy child, with well characterised uninjured vesicles;” we may “avoid taking matter from cases of re-vaccination;” in short, we may do exactly what we are told, and yet, after all, fail in consequence of the many imperfections attending the State mode of conducting vaccination. Where are our vaccination stations in country districts? and where the means for the fulfilment of the request of arm to arm vaccination? Nowhere but in paper. Proper well ventilated stations should be provided. I consider five shillings the lowest consistent fee to be offered for this highly important operation. Another great difficulty presents itself in our present system, how are we to examine a mother accurately in the most delicate points concerning health before a crowd of eager listeners? Can we expect an honest answer to interrogations that ought always to be asked and answered before we can advise about the best course to pursue relative to selection of lymph? In private, will a parent verbally confess to past syphilis? or gonorrhoea? or a dissolute life? or even a scrofula? In public it is not right to put the mother to the test. There is a simple way of overcoming this trouble, and that is to devote a special column in the ordinary vaccination paper, to half a dozen leading questions to be confidentially “filled up” by the parents prior to its delivery to the surgeon for his sole use, and under the seal of professional secrecy. Questions such as these—past and present health of parents? Has either had any disease contracted by impure conduct?

Scurvy—scrofula—consumption—bad disorders. Any of the immediate relations had these? ever had any extensive eruption? of steady habits of life? One is less likely to hear the truth about the baby. A few plain questions concerning it may not, however, be thrown away. The present arrangements for public vaccination in certain country districts cannot be carried out; although the population of the Sandham and Calverton districts, Notts, is only about 7,000, and my residence, central, instead of having one vaccination station, I profess to hold no fewer than seven. Shall I add that arm to arm vaccination is under these conditions impracticable; in fact, one station, if a small surgery can be titled a station, is alone attended. A few suggestions may be here applied to my own case. No reasonable man could expect a woman to trudge from village to village with a baby in her arms (putting its weight out of the question), exposed to all kinds of inclement seasons. Where the child's parents reside above a mile from the station, the State might hold the parish bound to provide a suitable conveyance for the infant and its mother, to and from their destinations. This is the only way to insure regular attendance, and a carrier's van in this place and that place would suffice for

the purpose. One might vaccinate from a central station on convenient days (quarterly) and a week before the appointed day, arrange to have four or five selected children vaccinated and ready for the occasion.

## Hospital Reports.

### MIDDLESEX HOSPITAL.

THE report of the Surgical-Registrar, Mr. Henry Morris, M.A., M.B. Lond., is as interesting as that of his colleague which we have on a former occasion epitomised. It appears that during the year 1870, 1,024 patients were admitted into the surgeons' wards; 139 remained in hospital on January 1st, 1870, and 19 were transferred from the physicians' wards. Total, 1,182. Males, 621; females, 561.

|                   |  |
|-------------------|--|
| Of these 917 were | discharged : recovered and relieved,   |
|                   | 819; unrelieved, 52; at their own      |
|                   | request or for other reasons, 46.      |
| 138               | remain under treatment.                |
| 13                | were transferred to physicians' wards. |
| 114               | died.                                  |

1,182

The mortality has been 9.6 per cent.—excluding cancers, 5.4 per cent. The greatest actual mortality has been amongst the cancer cases. The greatest relative mortality (*i.e.* relative to the number of cases) has occurred in fractures of the skull. Several cases enumerated in the table have been under treatment more than once, and the same case, in many instances, appears under more than one of the headings: thus, some have been discharged at own request, or for other reasons unrelieved, who have again been admitted, to leave recovered or relieved, or are still under treatment: others have been relieved on one or two occasions, and finally have been discharged unrelieved. Some few cases, which are not cancer, are included under the heading of malignant disease, such as sarcomatous tumours. When a patient was admitted suffering from more than one injury or disease, the case is entered under the heading of the injury or disease which was most prominent at the time of admission. It will be seen that, of the injuries, those which have occurred most frequently are (1) scalp wounds, (2) fractures of the ribs and fractures of the shaft of the femur, (3) scalds, (4) contusions of the back and of the lower limbs. Amongst the diseases, after cancer, come in order of frequency (1) ulcers, (2) diseases of the eye, (3) constitutional syphilis, (4) superficial abscesses and diseases of the hip-joint.

There seems to be a good deal of care bestowed on the cancer wards. The term cancer is used to express a morbid growth having the clinical features of malignancy rather than a definite anatomical structure; the harder and softer forms of the growth being distinguished by the usual names, *scirrhous* and *medullary*. As in former reports, to these names have been added *melanosis*, *epithelioma*, and *rodent* (commonly known as rodent ulcer), as each expresses a definite form of the disease spoken of as cancer. From the great difficulty of determining the precise form of the disease as it affects the womb (even with the advantages of post-mortem dissection and microscopic observation), the name *uterine cancer* is applied to all indiscriminately, but Mr. Morris gives in his tables special columns showing in which cases glandular affection, and in which secondary deposits in remote viscera were found after death. No special note of treatment (beyond mention of operation) has been tabulated; but it may be observed here, that it is the custom (to which there have been but few exceptions during the past year) in the Middlesex Hospital, to sponge into the fresh

wound, after removal of cancer, a solution of chloride of zinc or sulphurous acid; also, in some cases, the wounds have been dressed on Lister's principle.

The subject of infectious diseases always claims the attention; and the surgical registrar of the Middlesex Hospital tells us that, of 14 cases of infectious diseases admitted during the year, 6 were phlegmonous erysipelas, 7 simple erysipelas, and 1 pyæmia. Of the 6 cases of phlegmonous erysipelas 2 died, 2 recovered, and 2 remained in on January 1st, 1871. Of the 7 cases of simple erysipelas 1 still remains, and 1 died from abscess of the lung, and hemiplegia caused by embolism of the vertebral artery.

Fifteen cases of infectious diseases originated in the wards during the year, 6 of which were erysipelas, 7 pyæmia, and 2 scarlet fever. The 2 cases of scarlet fever occurred in Percy ward, and were removed as soon as the disease declared itself. Of the cases of erysipelas 3 of them occurred in three different wards (Regent, Queen, and Clayton) within 48 hours of each other. This was in the month of February. Of the 7 cases of pyæmia 2 obtain special notice from the registrar.

W. W., 896, was admitted in November, 1869, for inflammation about the right knee-joint, the result of an injury. On Feb. 15th a piece of necrosed bone was removed from the head of the tibia, after which he had rigors, sweats, and feverish symptoms, and abscesses formed in the limb. Amputation was performed on March 30th. Fresh abscesses formed in the thigh and back; but he ultimately recovered, and left the hospital on June 22, 1870.

W. S., 791, was admitted on October the 5th, for suppurative inflammation of the knee-joint. When convalescent, and about the ward with ankylosis of the joint, he was seized with typhoid fever, from which he recovered. Suppuration occurred about the joint when recovering from the fever, and pyæmia followed, from which he died. At the post-mortem examination abscesses were found in the right lung, and a large clot in the right femoral artery.

As compared with the year 1869, pyæmia has been more than double as frequent, while the number of cases of erysipelas has been just one half. Pyæmia originated in the surgeons' wards three times in 1869, as against seven times in 1870.

*Hernia*.—During the past year, of the 19 cases of hernia which were admitted to the hospital, 13 were strangulated, 5 were irreducible, and 1 reducible; the patient in the last category was admitted for continued vomiting, which, in his condition, had alarmed him.

Of the 13 cases which were strangulated 5 were femoral and in females, 3 being on the left side of the body and 2 on the right; 6 were scrotal, 3 on the right and 3 on the left side, 1 of them was congenital in a child of 9 months old; 2 were oblique inguinal, on the right side, and in males. Of the 5 irreducible cases 3 were umbilical (2 females, 1 male), all of which left the hospital unoperated upon; 1 was femoral (female), 1 inguinal (male); both of these were reduced by taxis. An operation was performed in twelve cases. In one it was exploratory, to examine the sac after reduction by taxis. In seven out of the eleven others, the sac was opened, and of this number 3 died. In 3 out of the 11 the sac was not opened, and of this number one died. In one case it is not mentioned whether the sac was opened or not. Taxis, with or without the previous use of ice, was successful in four cases, 3 of which were of long standing, and one congenital; they were—one irreducible femoral, one strangulated scrotal, one irreducible oblique inguinal, and one strangulated congenital scrotal. The average time of existence of rupture in the strangulated cases was ten years one month; the longest time 30 years; the shortest one year. The average duration of symptoms of strangulation before admission was 37 hours; the longest time 5 days; the shortest 4 hours.

**Compound Fractures.**—Ten cases of compound fractures were admitted to the Middlesex Hospital during the year; six were fractures of the leg, two of the arm, one of the middle of the thigh, and one of the fingers. Of the six cases of compound fracture of the leg, the seat of fracture was in one case in the lower third of the tibia, in two cases about the junction of the lower and middle thirds of the tibia and fibula, in two cases in the middle third, and in one case a Pott's fracture. Of the two cases of the arm one was at the lower third, and the other a case of fracture of radius and ulna into the elbow joint. In all the cases the treatment of the wounds consisted in the thorough washing out with sulphurous acid, or chloride of zinc lotions, and the application of carbolic dressings. In one case of fracture of the leg secondary amputation was required ten days after the accident for extensive diffusive suppuration of the limb. In another case portions of the upper extremities of the radius and ulna were removed, and a good recovery made, resulting in a useful moveable joint. In another case, besides compound fracture of the forearm, with extensive destruction of soft parts and much bleeding, there was a simple fracture of the humerus; primary amputation below the elbow was performed directly after admission. Death occurred only in one case, and in that the fracture was complicated with phthisis. The average time under treatment was 67 days.

**Post-mortem Examinations.**—One hundred and fourteen patients have died in the hospital during the year, of which cases 91 were examined after death. Fifty deaths from cancer occurred, 22 of which were cancer of the uterus, 13 cancer of the breast, 9 epithelioma, 3 cancer of the rectum, 2 rodent cancer, and 1 melanosis. Nine deaths from injuries to the head, of which 6 were fractures of the skull. Ten deaths from pyæmia and erysipelas, of which 7 were due to pyæmia. Three from wounds of the abdomen and viscera, every case admitted for this cause was fatal. Five deaths occurred in cases admitted for hernia, of which 4 were due to peritonitis, and 1 to internal strangulation unconnected with hernia.

## SCOTLAND.

**EDINBURGH LADY MEDICAL STUDENTS.**—Miss Jex Blake has addressed the Senatus of the University in her own name and in the name of the other four ladies who have completed the first half of their medical course, requesting the Senatus to take into immediate consideration what means are to be adopted to enable them to complete their education in the University. The following suggestions are made by Miss Blake:—

1. That whenever a Professor may be unable or unwilling to deliver a separate course of lectures on his subject, the Senatus should nominate for the approval of the University Court a special lecturer on the said subject, for the express purpose of giving us the requisite qualifying instruction, we undertaking to defray the expenses of such appointment; or

2. That the University regulations with respect to extra mural classes be so far relaxed in our special case, that, whenever a Professor may be unable or unwilling to deliver a separate course of lectures we should be authorised to attend a corresponding class in the same subject in the extra mural school, the said class being held to qualify equally for graduation.

The Senatus deferred consideration of the letter until the opinion of council could be obtained as to the legal powers of the Senate to deal with the above suggestions.

## The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 12, 1871.

### THE MEDICAL COUNCIL.

THE meeting of the General Medical Council this session in its own dingy lodgings in Soho instead of in the hall of a Royal College will probably be considered by many as an emblem of its fall in the estimation of the Profession. There can be no doubt that great hopes were once entertained of this cumbrous body, and that most of these hopes—wise or unwise—have been grievously disappointed. With every wish to do justice to all we cannot disguise the fact that the mass of the Profession cares less and less for the debates of its council, and that the only point in which much interest is likely to be evinced, in the unreformed Council, is the amount of money abstracted from the pockets of medical men it manages to squander.

What has been done? We will here give a few notes about the proceedings.

#### NEW MEMBERS.

Two new members took their seats. Mr. Quain for the London College of Surgeons—the nominee of the Council of that College—which denies even its Fellows a vote in the election of the representative. Mr. Quain is a worthy representative of the Corporate Committee of which he is a member, but he has not been elected by the Fellows and Members of the Colleges. They have no part nor lot in the matter. Would not such a man as Mr. Quain rather represent a constituency of thousands than of twenty-four?

Dr. Gull appeared as the Crown nominee to succeed Dr. Rumsey. The acceptance of the post by Dr. Gull has caused great surprise. One of the busiest physicians in London, with whom it is often difficult to make an appointment within a reasonable time, he seems prepared to spend days in medico-political talk, although he has never given reason to suppose he is interested in the questions involved. The popularity of Dr. Gull both with the public and the Profession may account for his being offered the post, though such appointments ought to be given

to those who have devoted themselves to medical politics. Dr. Gull would confer an infinitely greater benefit by giving the time and energy that will be lost in the Council to preparing for his brethren some of the clinical lessons of his rich and ripe experience.

#### THE MEDICAL BILLS.

These were several times alluded to, and a considerable time—which in this case means money—was wasted in repeating what was well known to all concerned. No progress can be made in Medical Reform until an extension of the suffrage shall make the Council representative of larger constituencies. It is disgraceful for a dozen or twenty men to be authorised to send one of themselves to pretend to represent a Collego or University.

#### PENALTY.

A petition was presented to restore a name to the Register, but was not acceded to. We note that the petitioner was said to hold a New York degree, but no one inquired how that was obtained. Now it happens that American diplomas are being sold in this country, and we should like to hear that the Council is cautious not to register degrees obtained without examination and proper education. It would be desirable to exercise great vigilance in reference to all foreign diplomas, and particularly when held by Englishmen.

#### PRETENDED "INFAMOUS CONDUCT."

We are glad to see that Mr. Kempster was acquitted unanimously of the charge brought against him—apparently by another practitioner—a "neighbour." The term professional brother may well excite the smiles of the public. The charge related to another person—an unqualified assistant—signing certificates of death; and practices well known to exist, whether right or not we do not now inquire, seemed to cause much surprise among the Councillors, who look over the heads of their humbler brethren, and seem to have no idea how any but "big-wigs" exist. But yet some of them have gone through other stages before reaching the dignity they now enjoy.

#### CERTIFICATES OF DEATH.

The Council seemed to ignore the fact that we and our contemporaries have frequently objected to the present form of certificate. We have often felt annoyed that we have been obliged to certify that a person died on such and such a day, when we only knew from the statements of others that death had recently taken place. It is not the practice to see the dead body before giving a certificate, and the Registrar ought to change the stupid form in which he has so long persisted. He ought not to ask us to certify the age of the patient last birthday—we can only do so on hearsay.

#### EDUCATION.

The Report on Education is the most important of the Session's work, and we shall return to it. Meantime we would say a word for students. They may be over-lectured in their short career. Would it not be better to prolong the curriculum rather than cram it with too much? Medical education is cheap enough in all conscience, and three years which some corporations accept is a very brief period to acquire the knowledge to fit a young man for practice. Even four years' hospital work is not much considering that those who take this are now avoiding the apprenticeship system formerly so common.

#### THERAPEUTICS.

The proposal to add a new compulsory course on this subject will not be looked upon with favour.

The remarks made shows the evil of having only men of the last generation in the Council. The lecturers on *Materia Medica* in the London schools are, some of them at least, doing much to supply what is wanted. They have made great advances in teaching their subject, and we should deprecate the separation of the Chair of Therapeutics from that of *Materia Medica*, which would thereby be rendered almost useless.

#### HOMŒOPATHY.—ITS PRINCIPLES EXPLAINED.

[The review of homœopathy which we commence the publication below requires a word of explanation. It was written many years ago by a gentleman who has since become well known in the literary world, and its interest is to some extent due to the fact that when he wrote it the author was thinking of entering the medical profession. The MS. has long been placed at our disposal, but in publishing it we are desired to state that the author never saw the late Dr. Epps, and only knew of his existence through his writings.]

ALTHOUGH the system of Hahnemann has been some time before the people of England we find many with scarcely an idea of what the word implies; others wishing for information, and some (of even those who have embraced it) entertaining the most mistaken notions concerning it. This however is not from want of means, for so much has been written on the subject that we should not have intruded our remarks if *homœopathists* had not asked for "some new mode of attack." We accept this challenge, and propose for "our" new mode of attack, instead of judging of the hydra, as a whole, to examine it limb by limb, throwing away those which prove to be the mere shadows of fancy. With these intentions we inquired for the clearest and best exposition of homœopathic doctrines, and were thereupon furnished with a small volume entitled "Homœopathy; its Principles Explained," by John Epps, M.D., &c.; and which proves to be a reprint of a course of lectures delivered by him in Exeter Hall. To this work we propose to direct our attention, NOT to give a hasty opinion on the whole, but patiently to weigh every argument, thoroughly sift every reason, and candidly examine every point Dr. Epps brings forward to support his views, and so place ourselves in a fair position to judge of homœopathy.

#### LECTURE FIRST.

THE first step Dr. Epps takes to vindicate his doctrine is to assert that the following axioms are unquestionable.

- 1.—"That truth has been discovered—at distinct and often distant intervals.
- 2.—"That the opposition, always created upon the discovery of truth, has been proportioned in intensity, strength, and amount, to the interests which the truth by the very necessities of its nature either must overturn, or appears likely to overturn.
- 3.—"That truth has ultimately triumphed."

Then comes the application.

Dr. Epps says: "Collect these axioms, apply them to homœopathy, and then will be seen why homœopathy was not discovered before; why homœopathy has been so violently and unfairly (!) opposed; and why we may hope a successful termination of the struggle." Sound logic this! But we first call upon Dr. Epps to

prove that homœopathy is identical with truth. Is it honest? Is it reasonable to suppose that if we admit axioms with regard to truth that we grant the same with regard to homœopathy, at the very time we are contending that the latter, in all its bearings, is utterly opposed to the former? Dr. Epps must first prove the identity, and we dare to prophesy he will have considerable difficulty in bringing "a successful termination to the struggle." If this be true logic every lie may as easily be proved as a problem of Euclid. If Dr. Epps thus proves his system of treating disease to be correct, why indeed may not Holloway or Coffin do the same? By such reasoning all quacks may be allowed to show "why their specific was not discovered before—why their patents are opposed and why they will ultimately be the only medicines employed." If this is their defence how can they complain of being "violently and unfairly (!!) opposed?"

The false insinuation (contained in his application of the second axiom) against medical men is too mean to require notice from that respectable body of gentlemen. Then comes the important question, "What is homœopathy." To answer this Dr. Epps finds it "necessary to make some inquiry respecting life; life and its modifications, health and disease, being the conditions with which homœopathy has to do."

Pursuant to this inquiry he rises from the mineral and vegetable kingdoms to the animal, at the head of which "stands man who possesses more manifestations of life than any animal, and has organs in proportion. When these organs all act in harmony with each other it is called health; when they act irregularly it is called disease." Thus he demonstrates that "health is life acting regularly and orderly; and disease is life acting irregularly and disorderly." This lucid and clear view of disease he informs us "being understood will destroy the notion that we can overcome disease." This "is a thousand destroying notion." Dr. Epps emphatically states it is, and to prove it so, argues "There is no self-existent, independent matter or thing called disease to overcome." What's in a name? if we alter its name from disease to "life struggling injuriously," as Dr. Epps has it; the thing is the same, just as the names of things in the *Pharmacopœia* have been altered times without number; but that does not alter the things themselves, nor is it an argument that they do not exist. As to the epithets self-existent and independent we consider them only applicable to the Deity.

The next step is a beautiful specimen of Dr. Epps's skill at portrait-painting. The picture is that of a medical man, and runs on thus:—"A dreadful warrior: he has hanging at his side a dreadful complement of sharp, cutting lancets; dangling from his belt he has a powerful cupping instrument; he carries a blister on his back; plaisters hang from his shoulders; skeins of thread and seton needles hang from his neck; issue-peas form bracelets round his wrists, &c., &c., &c." Such is the picture and it is well calculated to alarm and impress the sensitive nerves of the more delicate sex; but, surely no man of ordinary sense would be frightened thus into homœopathy.

Strange, too, but true it is, that no longer than five or six years before this was penned, this same Dr. Epps should have written a work expressly recommending such means of cure. Each and every one has been his favourite in turn, and now he discards and despises all. We have his own testimony \* that these "dreadful implements" have in his own hands worked the most surprising cures; but, like a fickle lover, when he leaves one object for another he must blaspheme the first. That praise is not worth much which can only be had at others' expense. Even more violent means than these have been a blessing to humanity. A violent surgical operation has saved many a valuable life, but homœopaths are so busily engaged in the estimation of the

effects of decillionths of a grain of inert substances, that they cannot descend to realities, and the world is obliged to submit to the judgment of those men, whom these highly intellectual gentlemen of the homœopathic persuasion politely inform that their experience for ages past is nothing, and that, labouring under error all their days, they have inflicted untold causes and miseries on their fellow creatures.

The public must judge between them. "Now," says Dr. Epps, "are there not means of cure which operate *tuto, cito, jucunde*." Of course there are, and as he himself says, "they have been collecting from the earliest ages;" but strange to say they are not included in his picture of the physician. Oh no! It is the homœopathist that employs "remedies" of this kind. Dr. Epps is not aware that long before "*similia similibus*" was thought of, or even Hahnemann lived "*tuto, cito, et jucunde*" was thought of as a motto continually acted on by physicians. He found the motto in his scrap-book perhaps, and so not knowing where he picked it up considered it as original; and, says he, "I'll act on it—its a good discovery." He does not know that sometimes the "*jucunde*," sometimes the "*cito*," must be sacrificed to the "*tuto*." It is all his own and fellow homœopathists' discovery.

(To be continued.)

## Notes on Current Topics.

### The Election at the College of Surgeons.

THE election to the Council of the Royal College of Surgeons of England took place on Thursday last. The result of the voting was—Mr. Spencer Wells, 131; Mr. Critchett, 130; Mr. Le Gros Clark, 127; Mr. Busk, 117; Mr. Barnard Holt, 104; Mr. Cock, 74. Mr. Spencer Wells, Mr. Critchett, Mr. Clark, and Mr. Busk were therefore declared duly elected to the vacant seats.

### The Small-pox Epidemic.

THE Registrar-General's last report states that the fatal cases of small-pox in London, which in the three previous weeks had been 245, 240, and 232, were 235 last week. The fatality from small-pox was greatest in Bethnal-green, Southwark, and Battersea, although the numbers showed a decline in the latter sub-district.

The returns of the number of fresh cases made by the relieving officers exhibited no important decrease up to the 24th of June. During the week ending on that day 545 fresh cases were returned.

### The Brown Bequest to the London University.

THE eccentric bequest to the University of London of a very large sum by a testator of the name of Brown, and the Parliamentary squabble to which it gave rise, will be in the recollection of our readers. It will be remembered that the will contained directions that the money should be applied to the establishment and maintenance of an infirmary for domestic animals; but that, if the London University failed to apply the fund to that purpose within a given period, the money should pass to Trinity College, Dublin. Although the London University accepted the bequest, yet when the expiration of the time set down for the carrying out of the

\* "On Counter-Action." By John Epps, M.D., &c.

trust approached, they were indisposed to apply the money in such a way, and introduced a Bill into Parliament to enable them to apply the money otherwise. But the Board of Trinity College, taking alarm, opposed the measure with such rigour that it was withdrawn.

It is stated now that a site for the requisite building has been secured, and its erection will commence at once. We imagine that it will turn out that a pardonable liberty will be taken with the testator's intentions, and that the institution which is about to be established will be rather a school of animal physiology than a cat and dog hospital.

### The Vaccination Question in St. Pancras.

At the last meeting of the St. Pancras Guardians the Clerk read a letter from Mr. Farris, secretary to the St. Pancras Ratepayers' Association, forwarding the following resolution passed by the Association:—

"The present changes made by the Board of Guardians, in their arrangements for public vaccination, are highly objectionable, inasmuch as the collecting together of a number of persons at stated times and certain stations has a tendency to spread infectious diseases, and fixing a time inconvenient for the working classes to attend. We are, therefore, of opinion that it would be more beneficial and more economical to place it in the hands of the district medical officers, as heretofore, and we are further of opinion that the reply received from the Board to our communication upon this subject, stating that the appointment of a public vaccinator was made at the request of the Privy Council, is unsatisfactory."

A deputation attended, and explained that it was impossible for working men to attend the vaccination station at eleven o'clock in the morning, and said they doubted if the Board were ordered by the Privy Council to appoint one vaccinator only, as it was a great inconvenience.

The Board, after a short discussion, agreed to hold a special meeting to consider this question, and it is to be hoped will rescind their *pet* arrangement, which has given the greatest dissatisfaction to the majority of the ratepayers of the parish, and if persisted in is sure to lead to disastrous consequences; notwithstanding the badger-hunting process lately adopted, to show off this "improved system," and thereby to stifle public opinion on this subject.

### Small-pox in Ireland.

No less than thirteen deaths from small-pox have taken place in the Workhouse Hospitals of Ireland in the course of the year 1870-71, in comparison with only one single case recorded in our last Report for the year 1869-70. The whole number of deaths by small-pox registered in Ireland in the year 1870 is known to be 32.

### Death from Nitrous Oxide Gas.

THE *Dental Cosmos* reports the case of a young lady in Philadelphia, who inhaled nitrous oxide gas, for the purpose of having a tooth extracted, and died in a few minutes. She had hypertrophy of the heart.

AN Examination of Candidates for Commissions in the Medical Department of Her Majesty's Army will be held in London on the 9th August next.

### Mortality in Irish Workhouses.

THE total number of deaths in fifty-two weeks has been 10,639. In the corresponding term of last year the total number of deaths was 10,968, which, compared with the present numbers, shows a decrease of 329 deaths, and a decrease of 810 compared with the number in the preceding year.

The number of deaths by fever is 630 in comparison with 774 in the previous year, and with 884 in the year preceding.

### Meat Preservation.

THE Food Committee of the Society of Arts has presented the following report:—

Your Committee report a great improvement in meats which have been preserved in tins. Both as to the quality of the meat, its appearance, and retention of nutritive qualities, there has been satisfactory progress, and the Committee regard this process as furnishing a very valuable aid to other kinds of food.

The trade from Australia in tinned meats has very largely increased, in the exportation both of beef and mutton; and, so far as the many specimens of this and other modes have been investigated by the Committee, this one alone has as yet fulfilled the necessary conditions of bringing meat from a distance with fully-retained meat flavour, without deterioration by addition of chemical agents. No process of the latter kind which as yet has been submitted to your Committee can be said to be thoroughly successful. Either the texture of the meat has been broken down or hardened, and the flavour destroyed or altered, and in many cases such a distinct saline or mineral taste added as to preclude the adoption of such specimens as articles of general consumption.

### Effects of Alcohol and Tobacco on the Sight.

DR. RICHARD H. DERBY, in a recent number of *N. Y. Med. Journal*, treats of colour-blindness and amblyopia thus caused, and says: "Almost always both eyes are affected. This form of amblyopia occurs almost solely in men; out of fifty-six cases only three were women. It is a disease of adults; its frequency increasing from the twentieth to the fortieth year. In a portion of the cases abuse of alcohol was certainly the cause of the affection, and in others the excessive use of tobacco undoubtedly contributed to produce the disease. Forster, in a paper on the injurious action of tobacco on the vision, attaches still greater importance to this agent as a cause of amblyopia, supporting the views of Mackenzie, Sichel, Hutchinson, Lureiro, and others. The author cites twenty cases, in which there was a central scotoma, with a horizontal diameter of 18° to 25°, within which large letters could still be recognised. All of these patients suffered from some affection of the digestive and nervous system. Loss of appetite, constipation, loss of sleep, were common symptoms. Each one of the twenty patients was a strong smoker, and in eleven of these cases a very marked improvement was observed when the use of tobacco was given up."

MR. CORRANCE, M.P., has given notice of his intention to move a resolution to the effect that it would be desirable to extend the provisions of the Irish Medical Charities Act to England.

### The Control of Dipsomaniacs.

A CONFERENCE on this subject took place with Mr. Bruce at the Home Office last week. The crying necessity for such a measure was strongly urged by Dr. Dalrymple, who introduced a deputation, viz.: Colonel Akroyd, Mr. Ernest Hart, British Medical Association; the Secretary to the Provincial Licensed Victuallers' Defence League; Mr. Watson, of the United Kingdom Alliance; Dr. Stallard; Dr. Rogers (Poor-law Medical Officers' Association); Mr. Miller, M.P., and Mr. McLaren, M.P. Mr. Bruce, in reply, yielded to no one in his desire to check habitual intemperance, but said this was one of the most difficult class of questions to deal with, and having carefully considered the Bill, and taken competent professional advice upon it, he had come to the conclusion that it was a measure that would not work. He therefore did not think the Government would be justified in allowing it to be read a second time. Still it was not to be concluded that, in opposing the Bill, he was of opinion the question was one not capable of legislation. If this Bill had been the law in former days, it was just possible one of the most distinguished statesmen of the last generation, as well as one of our greatest poets, would have been liable to be shut up as habitual drunkards. It must also be remembered that legislation of this kind ought not to be confined to drunkards, for habitual gamblers, and seducers of female virtue were equally devoid of self control, and inflicted the same, if not more misery, upon the world. Probably it would be a greater advantage to society that they should be shut up first, but all these classes should be legislated for not singly, but as a whole, though, perhaps, that of the confirmed drunkard was the most pressing. He would suggest that as the question had not yet been thoroughly considered in all its bearings, an inquiry should be made as to what was doing in the matter, both in this and other countries, with the view of ascertaining the results and extent of the cures obtained. Let the Bill, after discussion, stop short of the second reading, and a select committee, to which he would give a ready assent, be moved for early next session, to inquire into the whole subject. That course, he thought, was the only chance of successfully accomplishing the object of the deputation.

### Medicine, "Going, going, gone!"

THE Board of Supervisors of Ohio county, proceeded to open the proposals of physicians to attend prisoners in the county jail and poor-house.

Dr. Reeves offered to attend the jail three times per week for 250 dols., or on former contract at 70 dols. per annum.

Dr. Jepson proposed to attend the jail for 59.50 dols. per annum.

Dr. Allen proposed to attend prisoners at 225 dols. per annum.

Dr. Storer proposed to attend the poor farm three times a week for 156 dols., Dr. English for 450 dols., Dr. Weeb for £149, Dr. Cracraft for 200 dols. three times a week, or 300 dols. for a visit every day.

Dr. Jepson's bid being the lowest for attendance at the jail, the contract was on motion awarded to him at 59.50 dols. per annum.

The *Philadelphia Medical Reporter* publishes the foregoing honourable record. May we commend it to the con-

sideration of the medico-ethical societies with whom rests the regulation of fees for clubs and contract doctoring. Would it not be a ready method of disposing of such transactions to set the medical remuneration arising therefrom up to Dutch auction, and of course accept the lowest bidder? To this complexion may we come at last.

### Lunatic Drunkards.

A MEETING, convened by the Licensing System Amendment Association, was held in support of the Habitual Drunkards' Bill. Dr. Dalrymple, M.P., its author, occupied the Chair, and explained the purpose of his Bill. He, however, had no hope of carrying it this Session. All he wished was to have it read a second time as a basis for complete legislation next year. Mr. E. Baines, M.P., moved, Mr. Barrow seconded, and Dr. Lush, M.P., supported a resolution approving the Bill, which was carried unanimously. Colonel Akroyd, M.P., proposed, Mr. Miller, M.P., seconded, the Rev. Mr. M'Naught, and Mr. R. Assheton, M.P., supported the proposition, which was adopted and at once carried out, that the gentleman present should go to the Home Secretary with a memorial.

At the last Medical Club dinner, Dr. Lush, M.P., presided, and was supported by Dr. Brewer, M.P.

In the Census Report, Dr. Farr says that though the people are still increasing, the products they create increase faster than their numbers.

The Council of University College Hospital has done a commendable act. It has conferred the title of surgeon on Messrs. B. Hill and C. Heath, thus following in the wake of some other London Hospitals.

THE *Journal of Cutaneous Medicine* is discontinued, and its editor, Dr. H. S. Purdon, will write a Quarterly Report on "Dermatology," which will appear in the *Doctor*, the new monthly journal of Medical Practice and Literature.

THE Annual Meeting of the Medico-Psychological Association will be held at the Royal College of Physicians of London, August 3rd, under the presidency of Henry Maudsley, M.D., F.R.C.P.

The members of the Association and their friends will dine at 7.30 at Willis's Rooms.

THE Irish Poor-law Commissioners' Report shows that the number of inmates of workhouses last February, is less by 4,227 than the number in the preceding year, and less by 6,693 than in 1869. At the latest date the decrease amounted to 4,013, or 7.4 per cent. less than in 1870, and to 7,261, or 12.7 per cent. less than in 1861.

The number of persons receiving out-door relief has increased, on the other hand, from 22,520 to 25,363 in the course of the year; but the Commissioners disregard any increase or decrease of out-door relief as indicative of the state of the population, and anticipate, as the country advances in prosperity, the out-door relief lists, which have steadily increased from 655 persons, daily, in 1855, to 25,363 in 1871, will continue to increase.

THE folly of the policy of those Medical Corporations which endeavour to attract candidates for their diplomas

by keeping at a low level the educational standard of their qualifications is strikingly illustrated by the number of entries which have recently been made for the preliminary examination of the University of London. The Examining Court of the University had incurred some opprobrium for their wholesale slaughter of half-educated candidates, and, of course, the speculators for a fall prophesied the ruin of the University if the ignoramuses were not tenderly dealt with.

The reply to such a forecast is that at the last entry six hundred and twenty-six names were given in—a number never equalled.

A conclusive proof that the day when it was bliss to be ignorant and folly to be wise has passed away.

## PROCEEDINGS OF THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

SESSION 1871.

JULY 4TH.

THE General Medical Council commenced its sittings this day. Dr. Paget, President, took the chair. Two new members were introduced: Dr. Gull, nominated by the Crown, in the place of Dr. Rumsey, resigned; and Mr. Quain, nominated by the College of Surgeons, in the place of Mr. Cæsar Hawkins.

THE PRESIDENT, in opening the session, referred to the personal changes in the Council, the withdrawal of the Bill recommended by the Council and adopted by Lord de Grey, and the business of the present session.

The usual committees were thereupon appointed. The returns from the Medical Department of the Army, and from the Medical Department of the India Office, were laid before the Council. The statement of the degrees, diplomas, and licences of the candidates for commissions in the Medical Department of the Army, who, in February, 1871, presented themselves for examination, showed that of the candidates there were 36 successful, and 21 unsuccessful. Of the unsuccessful, 17 would have been accepted had there been vacancies for them. The qualifications held by those who "failed" were those of the Edinburgh College of Physicians in 1 case, the Edinburgh College of Surgeons in 1 case, in 3 cases the King and Queen's College of Physicians, and in 3 the College of Surgeons of Ireland. The statement of the degrees, diplomas, and licences of the candidates for commissions in the Medical Department of the Indian Army, who, in February, 1870, presented themselves for examination, showed that of the candidates there were 10 successful, and 13 "failed." The diplomas and degrees of the successful candidates were 21, and of the "failed" 26. Of the 13 candidates returned as unsuccessful, 9 were qualified, but were not accepted, as only 10 appointments were made. The "failed" candidates possessed chiefly the diplomas of the Royal College of Surgeons of Edinburgh, of the King and Queen's College of Physicians of Ireland, of the Royal College of Physicians of Edinburgh, and of the College of Surgeons of Edinburgh.

In reply to questions, the president said he had no official information about the Medical Bill, and he read Mr. Forster's words from a report of the debate in the House of Commons. "Mr. Forster said that legislation had failed last year because, although the Bill which had been introduced in the House of Lords had been most carefully considered, it had been thought desirable when the Bill came down to that House (the House of Commons) to add to the question they were then attempting to settle the other question of the constitution of the Medical Council, and it was then too late in the session to deal with that subject."

A list of examining bodies whose examinations fulfil the conditions of the Council was laid upon the table.

The following report of the Educational Committee was read:—

### REPORT OF THE COMMITTEE ON PROFESSIONAL EDUCATION.

The Report of the Committee of 1869 on Professional Education, and the replies to the letter of the chairman from teachers on medical education, were forwarded to the licensing bodies, and answers were received from them in 1870. All the answers did not arrive in time to be presented at the meetings of the Council in 1870, and accordingly an interim report only was then laid before the Council (Minutes, vol. viii. p. 11). By a resolution of Council (Minutes, vol. viii. p. 105), the Committee on Education was reappointed, and directed to report at a future meeting of the Council.

The probability that an Act to regulate medical education would be passed in 1870 rendered it inexpedient to discuss last year many of the suggestions contained in the Education Report, and in the replies sent in by the licensing bodies; for if the Medical Bill of 1870 had been passed, it would have necessitated a revision of the whole subject of medical education and examination, and would have rendered any previous decisions null and void.

During the last two years very important alterations have been made in the system of education and examination by some of the licensing bodies, and several of the suggestions of the Education Committee have been met.

The Royal College of Physicians of London, by a rule passed in April, 1871, requires from every candidate for its licence evidence that he has discharged the duties of clinical clerk and of dresser for periods of three months respectively, and thus one important recommendation of the Education Report has been carried out.

The Royal College of Surgeons of England, on the reception of the report, appointed a committee to consider it, and eventually determined to act on the opinion of their Court of Examiners of the 16th December, 1869, that "every part of the knowledge included in, or accessory to, the education of candidates for the diplomas of the College ought to be taught and learnt practically." The College has, therefore, introduced into its curriculum clauses which insure practical instruction in chemistry, pharmacy, general anatomy, and physiology and surgery, and has ordered that every candidate at an early period of his hospital attendance shall be individually engaged at least twice a week in the observation and examination of patients, under the direction of a recognised teacher, during not less than three months; this is for the purpose of enabling him fully to profit by the hospital instruction. And, in addition to this, every candidate is ordered, as formerly, to be also a dresser, or to have charge of patients equivalent to the work of a dresser, for six months, and is also to attend demonstrations in the *post-mortem* rooms of a recognised hospital during the whole period of surgical hospital practice. And to ensure that these regulations shall be carried out, the College has now instituted for the diploma of membership (as it had previously done for its fellowship) a practical clinical surgical examination, in addition to the examination in bandaging, &c., formerly instituted.

The Society of Apothecaries of London has also made some important changes. Since June, 1870, all candidates have been required to produce evidence of having served the office of clinical clerk for at least six weeks, and of having been examined at the class examinations conducted by the teachers of the respective subjects. The clinical examinations which were instituted by the Society on the 13th June, 1867, have been made an integral and invariable portion of the final examination. Students attending for their first or primary professional examination have been required, since December, 1870, to undergo an examination on medical regional anatomy on the healthy subject; and in various other parts of the examinations increased practical work has been demanded.

It is possible to overrate the effect which the regulations of these great licensing bodies (to whom the majority of English students go for their licences) will have on medical teaching in England. A great part of what was desired by the Committee of Education has been thus obtained, and it seems only just that the Council should fully recognise the improvements which have been made.

The four English Universities have made no change in their systems of examination, which were considered satisfactory by the Council.

In Scotland the Royal College of Physicians of Edinburgh now requires all candidates for the licence, without exception, to undergo a clinical examination in medicine in the Royal

Infirmary of Edinburgh; previous to July, 1869, students only underwent this test.

The Royal College of Surgeons of Edinburgh had, previously to July, 1869, instituted practical clinical examinations, which are carried on in a surgical hospital, and they have since made no change in their regulations.

The Faculty of Physicians and Surgeons of Glasgow has not essentially altered the mode of conducting the examinations, but in some points the examination has been more systematised, especially as regards the clinical part. All candidates, whether previously qualified or not, are subjected to an examination at the bedside, both in medicine and in surgery. The written part of the examination has also been extended.

The University of Edinburgh has made no alteration.

The University of Aberdeen has annulled the regulation which exempted the candidates who obtained the highest place in the written examination from being examined orally, and, in accordance with the wish of the visitors from the Medical Council, enforces the oral examination on all.

The University of Glasgow has made the clinical examination more efficient, but otherwise has made no change.

The University of St. Andrews has made no alteration.

In Ireland, the University of Dublin has improved the clinical examination, and now systematically enforces it on all candidates. The previous medical examination (viz., in physics, chemistry, botany, materia medica, and descriptive anatomy) is now compulsory.

The Queen's University in Ireland has instituted clinical examinations in medicine and surgery in the final examination for the M.D. and Master in Surgery.

The Royal College of Surgeons of Ireland has introduced a practical examination in bandaging, &c., and the Council is now engaged in the consideration of how best to introduce clinical examinations in surgery.

The King and Queen's College of Physicians has instituted a clinical examination, which is carried on in the wards of a hospital, for the second or final part of the examination.

The Apothecaries' Hall of Ireland has extended the period of examination from two to six days, so as to more practically test the candidate's knowledge; and it has instituted a clinical examination of patients, which is enforced on all candidates.

It cannot be doubted, from the previous statements, which have been drawn from official communications received from each licensing body, that great progress has been made in the path indicated in the various reports of the visitors of the Medical Council and of the Committee on Education. It cannot be for a moment supposed that those alterations are made in the letter only, and are illusory. We believe that they are what they profess to be; and, believing this, we must allow that the licensing bodies have shown a determination to improve their curricula and examinations, and that in several cases both are now much more efficient than formerly.

There are, however, some suggestions in the Education Report which have not yet been carried out, and on which it seems desirable the Council should express an opinion; while there are other suggestions which it will be better to keep in abeyance until the medical legislation, which cannot long be delayed, has been concluded. Of the former kind there are some of considerable importance:—

1. The separation of the teaching of pharmacy and therapeutics, the former being made an early and the latter a late course in the curriculum. The opinion of the Committee on Education, which included Dr. Christison and Dr. Aquilla Smith, and the views of all the best teachers of materia medica, were in favour of this separation. But some licensing bodies consider that therapeutics should not form the subject of a separate course of study, but should be considered an essential part of the courses on practical medicine and surgery. It must be admitted to be so, but still there is a necessity for special instruction, and without it, it may be confidently asserted that the progress in therapeutics will be slow. It seems desirable that a definite opinion should be come to on this point, and we propose to move a resolution to take the sense of the Council on this matter. So also, it will be for consideration how far practical instruction in drugs and pharmaceutical preparations might not be substituted for formal lectures. For the last two sessions a plan of the kind has been carried on by Dr. Harvey, at Aberdeen, and is said to have been highly successful.

2. The length of time assigned to midwifery in most of the present curricula is too short, and the Committee on Education recommended that one entire winter session should be assigned to this subject, and that the amount of practical instruction should be increased. This opinion was shared by all the experienced teachers in midwifery, whose replies are given in the appendix to the Education Report of 1869. We therefore advise that the Council shall recommend that the systematic lectures on midwifery shall be given in the third or fourth winter course, and that the candidates shall be required to attend not less than twenty labours in addition to practical instruction in the diseases of women.

3. The recommendation that pathological anatomy shall be made a separate course has not been carried out, but several of the licensing bodies have endeavoured to meet it by requiring a certificate of attendance, and of practical instruction in the dead-house. We think that a certain number of systematic lectures should be added to this practical instruction.

4. The Committee on Education strongly advised the enforcement of more regular class examinations. The Society of Apothecaries of London has ordered that all students shall produce evidence of having undergone these examinations, and we advise the Council to urge on all the licensing bodies to issue regulations requiring that written class examinations shall be frequent.

The other points raised in the Education Report, and which we advise should not be discussed at present, are—the length of the sessions, the method of teaching chemistry, and the application of chemistry, physiology and pathology, the teaching of minute anatomy, and the definition of the areas of instruction and of examination.

The new curricula, especially that of the College of Surgeons of England, will gradually introduce changes in some of these matters; and the probability of parliamentary legislation on medical examinations renders it now inexpedient to deal with the remaining questions.

The allusion to possible legislation leads us to the last part of the Report of the Education Committee of 1869. The Council will doubtless remember that the Committee strongly recommended the formation of conjoint examining boards, so as to reduce the number of licenses to practise from nineteen to three, and to make each license a qualification in both Medicine and Surgery; that the Council authorised circulars to the licensing bodies in this sense, and that in the autumn of 1869 various conferences took place between some of the licensing bodies, and replies were received from many of them favourable to the proposed combinations. Subsequently the action of the Government in introducing a bill to carry out the same object suspended all negotiations of the kind. The withdrawal of the Government measure in consequence of the opposition raised on another ground has replaced matters on the old basis.

It might indeed be argued that the willingness of the licensing bodies to improve their examinations, and the fact that they really have improved them, renders it less necessary to revive the plan of a single uniform license to practise for each division of the kingdom. But a moment's reflection will show that the proposal is still necessary. The independent licenses and their several examinations still remain as numerous as ever. The competition between different bodies, therefore, still exists, and must produce its fruits, and the inequality of the examinations in different parts of the kingdom remains.

Any licensing body raising its standard beyond a certain point will certainly drive some students, who otherwise would take its license, to more lenient bodies. The rigour of an examination may then exist only on paper, and all the efforts of the Council may be spent in making ropes out of sand.

The only effectual remedy, unless the Council is prepared to be constantly inspecting and visiting the examinations of the licensing bodies on a more systematic plan than heretofore, is to urge on the system of a single portal for each division of the kingdom.

The discussions of the last two years have shown that there are no insurmountable difficulties. In England the three great licensing bodies have, at the instance of the Royal College of Physicians, almost arranged a scheme, and it seems to require only a little more aid to form a single board for England. In the other divisions of the kingdom enough has been done to show that combination can be carried out if men will earnestly try for it.

It is impossible that the Government, after introducing a bill, should let the matter entirely drop. If it did so, the present session has shown that there are persons ready to take the matter up; and if the licensing bodies do not themselves carry out a measure of the kind, they will give great discouragement to those who desire to see them continue the representatives and guides of the Profession, but who consider the thorough examination of those on whose skill the lives of men are to depend must be provided for at all costs.

The Council can hardly, without inconsistency, leave the resolution of the 26th February, 1870, to remain a dead letter. In this resolution, which was carried by fifteen votes against three, the Council decided that it was of opinion a joint examining board should be formed in each division of the kingdom. Subsequently, also, the Council passed a resolution approving of the principles of the Medical Bill which was at that time being prepared by Lord de Grey. Accordingly, we beg to recommend that the Council shall address a letter to each licensing body, transmitting a copy of the resolution of the 26th February, 1870, and urging that arrangements for the formation of the boards shall be undertaken without delay, so that the Council may be in a position to communicate them before the close of the year to the Government. And we advise, in addition, that the Council shall authorise the Executive Committee to seek an interview with the Lord President of the Council, and to urge upon him the desirability of such medical legislation in the session of 1872 as may carry out the object the Council proposed in passing the resolution of February, 1870, and which Lord de Grey had in view when he introduced his Medical Bill of 1870.

(Signed) E. A. PARKES, *Chairman*.

On the motion of Dr. QUAIN, the name of Edwin Lowe, who had been convicted of felony was ordered to be removed from the Register.

A motion was being made that Henry Morris be removed from the Register, and was referred to the solicitor of the Council.

A petition was read from Dr. Pattison, M.D. of the University of New York, praying that his name might be reinstated on the register.

On the motion of Dr. STOKES, seconded by Dr. A. SMITH, the following resolution was passed:—"Having heard the petition of Dr. Pattison to be replaced on the Register, the Council see no reason for reversing the decision to which they formerly came after a full and careful consideration of the whole case."

A letter was read from Dr. Edwards Crisp, enclosing copy of resolution passed at a meeting of Medical Practitioners held at Freemasons' Hall on May 7th, 1870. The Registrar was directed to acknowledge the receipt of the communication, and say that it had been read to the Council.

A letter was read from the Board of Public Examiners, Cape of Good Hope, praying that the Council would be pleased to recognise their third-class certificate in literature and science, which had been assimilated to the matriculation examination of the London University, as fulfilling the conditions of the Council with respect to preliminary examination. The subject was referred to a committee.

A letter was read from the Honorary Secretaries of the Sydney Infirmary and Dispensary requesting advice on the subject of founding a medical school at Sidney. On the motion of Dr. FLEMING, seconded by Dr. HUMPHRY, a resolution was passed stating that it was not in the province of the Council to give advice on such matters, and referring the writers to the Council's reports and other proceedings on medical education.

THE RETURNS FROM THE ARMY AND INDIAN MEDICAL BOARDS.

DR. ALEXANDER WOOD called the attention of the Council to the returns from the Army and Indian Medical Boards, and moved that they be referred to a committee to report upon them to a subsequent meeting of the Council.

After a discussion this resolution was adopted, and the Council adjourned.

JULY 5TH.

The Council reassembled at two o'clock; Dr. Paget in the chair.

THE CASE OF MR. KEMPSTER.

The Council investigated the case of Mr. William Henry

Kempster, of Battersea, who had been summoned to appear before the Council on a charge of "infamous conduct in a professional respect."

Mr. Kempster was in attendance, and was accompanied by Dr. J. B. Langley, Dr. James Joseph, Mr. W. G. Sutcliffe, and Mr. Wm. Goodson.

After full investigation of the accusation, which was that he had allowed another person improperly to sign certificates of death for him, he was unanimously acquitted.

MR. KEMPSTER thanked the Council for the impartial hearing given to his case.

Sir D. CORRIGAN then proposed the following resolution: "That the facts which have come to the knowledge of the Council in the investigation of the case of Mr. Kempster have impressed the Council with the conviction that an amendment of the laws in force in regard to death registries is most urgently required, and that a copy of this resolution be forwarded to the Secretary of State for the Home Department."

DR. CHRISTISON seconded the motion, which was unanimously agreed to.

A report was presented by the Committee to whom was referred the application from the Board of Examiners at the Cape of Good Hope, recommending that their third-class certificates be recognised, the examinations corresponding with the matriculation examination of the University of London.

The Council then adjourned.

JULY 6TH

The Council considered a motion of Dr. Parkes, seconded by Dr. Christison, for the separation of instruction in pharmacy from that in therapeutics. Complaints were made as to the little attention paid to therapeutics in medical schools; and it was urged that it should form a subject of separate systematic instruction at a late period of the medical curriculum. It was contended, on the other hand, by Dr. Humphry, Dr. Apjohn, and others, that the proposal would be unnecessarily adding to the already heavy burden laid on the shoulders of students. After a lengthened discussion, the motion was carried by a considerable majority.

Another resolution of Dr. Parkes, for the extension of the instruction of midwifery, to include the diseases of women and children, was strongly opposed as being unnecessary and inexpedient, and was rejected by the Council.

A third resolution was moved by Dr. Parkes, "That it is desirable that instruction in pathological anatomy should include a certain number of systematic lectures." To this an amendment was moved by Dr. Humphry and carried, "That it is desirable that systematic instruction in pathological anatomy should form part of professional education."

A fourth resolution, moved by Dr. Parkes and seconded by Dr. Humphry, "That it is desirable that class examination should be compulsory on students, and that the licensing bodies should require them in all cases," was met by an amendment by Sir D. Corrigan (who objected to the term "compulsory"), "That it is desirable that class examinations should form a part of every course of lectures, whether systematic or clinical." The amendment was rejected, but another amendment was carried, moved by Mr. Quain, "That it is desirable that class examination should form a necessary part of every course of instruction."

JULY 7.

DR. BENNET made a statement in reference to the arrangements for a Conjoint Examining Board for England, agreed to by a Conjoint Committee of the Royal Colleges of Physicians and Surgeons of England.

A discussion next took place on Clinical Instruction in Medicine and Surgery, but no resolution was agreed to.

The same result followed a discussion on the propriety of students having the option of acquiring an adequate knowledge of Chemistry, and of passing an Examination in it, before they enter upon the period recognised by the Licensing Bodies as the course of Professional Study.

On the motion of Dr. PARKES; seconded by Dr. SPORRAR; it was then resolved "That a letter be addressed to each Licensing Body transmitting a copy of the Resolution of the Council of the 26th February, 1870 (see vol. viii., pp. 32-4), on the formation of Conjoint Examining Boards, and urging

that arrangements for the formation of such Boards should be undertaken without delay, and should be communicated to the President of this Council before the close of the present year."

It was moved by Dr. PARKES; seconded by Dr. ANDREW WOOD; and agreed to:—"That the following resolutions passed in February, 1870, be transmitted to the Licensing Bodies:—

#### 1. RESOLUTION OF THE 26TH FEBRUARY, 1870.

"That this Council is of opinion that a Joint Examining Board should be formed in each of the Three Divisions of the Kingdom, and that every person who desires to be Registered under any of the Qualifications recognised in Schedule A to the Medical Act, shall be required, previously to such Registration, to appear before one of these Boards, and be Examined on all the Subjects which may be deemed advisable by the Medical Council; the rights and privileges of the Universities and Corporations being left, in all other respects, the same as at present."

#### 2. RESOLUTION OF 28TH FEBRUARY, 1870.

"That in accordance with the foregoing Resolution (*see* vol. viii, p. 32, Sect. 2), the Universities and Medical Corporations established in each division of the United Kingdom, shall be requested to concert a Scheme for the constitution and regulation of a Conjoint Examining Board for that part of the Kingdom to which they belong, and shall, on or before June 1, 1870, transmit such Scheme to the consideration of the General Medical Council."

#### JULY 8TH.

1. Moved by Dr. ANDREW WOOD; seconded by Sir D. CORRIGAN; and agreed to:—"That the Registrar be directed to erase from the Register the name of Frederick Henry Morris, of Swindon, Wilts, the Council being satisfied that he is the same person who was convicted at Devizes, on the 27th day of March, 1871, of misdemeanour, and of whose conviction a legal certificate has been submitted to the Council."

The Report of the Committee on the application from the Board of Public Examiners of the Cape of Good Hope, was then received and adopted.

It was agreed to refer to the Executive Committee to report on the most desirable mode of procedure in the case of motions having reference to any penal measures.

The report of the Finance Committee was then read and adopted.

#### REPORT.

The Finance Committee beg leave to present, in the table subjoined, a statement of the income and expenditure of the year 1870, compared with the income and expenditure of the preceding year, also an estimate for 1871.

It will be seen that there has been an increase of income in 1870, and that this is partly due to an increase in the number of Registration fees; but it includes also the balance of the Pharmacopœia account and the proceeds of sales, making together £607 6s., which, by direction of the Council, is now included in the ordinary income. The debt still owing to the Council on account of the Pharmacopœia was reduced in January last to £104 14s.

The expenditure of 1870 is less by £302 13s. 8d. than that of 1869. The reduction is to a considerable extent due to a diminished charge for printing, especially for printing Reports of Committees. It is expected that a considerable permanent saving under this head of expense will be effected by an arrangement that has been entered into for printing and binding the *Medical Register* at a reduced cost through the agency of Her Majesty's Stationery Office.

Dr. SHARPEY having signified his desire to resign the office of Treasurer, a vote of thanks to him for his long and valuable services was passed by acclamation; and Dr. Bennett was afterwards elected Treasurer.

The committee appointed July 4th to consider and report on the Returns from the Army and Indian Boards presented a report recommending that communications be addressed to the Director-General of the Army Medical Department, and to the Major-General, Military Secretary, India Office, suggesting an alteration in future returns to prevent the misunderstandings that have sometimes taken place.

The Report of the Pharmacopœia Committee was next read and adopted. It recommended that the present arrange-

ments should continue. The Pharmacopœia Committee of last year was therefore re-appointed.

It was resolved—"That it is desirable that the Visitation of the Preliminary Examinations and those of the Licensing Boards be recommenced, and that a committee be appointed to consider the best means of doing so. The Committee to consist of Dr. Alexander Wood, chairman; Dr. Humphry, Dr. Thomson, Mr. Quain, Dr. A. Smith, Dr. Sharpey, and Dr. Storrar."

#### CURRENT LITERATURE.

#### PUBLIC SCHOOL REFORMS.

IN the midst of the cricketing season, we may direct attention to a pamphlet under this title, by M. A. B\*, a signature well known to those who take an interest in this and other important social questions. The pamphlet is full of practical suggestions and sound advice on the mental, moral, and physical training of youth, and should be read by both teachers and parents.

THE "Dental Profession"† by a dental surgeon, is the title of a pamphlet containing an excellent letter to a London newspaper, protesting against the insertion of puffs of quack dentists such as that to which we not long since directed attention. The letter is temperate and just, and the author deserves the thanks of his brethren for this vindication of their honour. Quacks perhaps abound more in the dental branch of our art than any other, and it seems to us desirable that a calm statement like the one before us should have a wide circulation. It shows that all sorts of artifices are resorted to by unqualified persons, to cause the public to confound them with qualified practitioners.

MESSRS. LONGMAN have issued a third edition of Dr. Mackenzie's work on "The Use of the Laryngoscope."‡ The two former editions have been highly spoken of by this journal as well as many of our contemporaries, and the work is now well known to the profession. We have only here to say that it has been carefully revised. Additional matter and new woodcuts also appear in this edition. We notice a sketch of the oxy-hydrogen lime light and chain as now used at the Hospital for Diseases of the Throat, and in the text a "Bibliography" naming all the important works on the subject.

MR. HOLT publishes a pamphlet on the "Selection of Trusses"§ which is worthy of notice, as the advice of one who has had large experience on a subject which is too often neglected, to the annoyance of both surgeon and patient.

#### OBITUARY.

#### THE LATE LIONEL JOHN BEALE.

THIS amiable practitioner died at the age of seventy-four, after an illness of only four days. For many years he had lived in Long acre. He was well-known and much esteemed. Of literary taste and retired habits he never sought extensive practice, but took such as came from those who knew him for his sterling worth.

He leaves one son who has made his name honourably distinguished by his physiological researches, and who is still physician to King's College Hospital.

\* "Public School Reforms." By M. A. B. London: L. Booth.

† "The Dental Profession." London: Hardwicke.

‡ "The Use of the Laryngoscope in Diseases of the Throat." By M. Mackenzie, M.D., Physician to the Hospital for Diseases of the Throat, &c. &c., 3rd edition, revised and enlarged. London: Longman, Green, and Co., 1871.

§ "On the proper Selection and Scientific Application of Trusses." By C. Houlhouse, F.R.C.S., Surgeon to Westminster Hospital, &c. London: J. and A. Churchill.

### PROTECTION FROM POISONING.

MR. FORSTER has, as we anticipated, adhered firmly to the intention expressed by him to the deputation of the Pharmaceutical Society—to carry through his Bill for the purpose of making poison regulations compulsory—but he has conceded many important amendments which he has embodied in an Amended Bill issued last week.

On Monday week in answer to a question from Mr. T. Cave, whether the attention of the Government had been drawn to the numerous petitions that have been presented against the Pharmacy Bill, and whether it was intended to proceed with the Bill during the present session,

He said the Government intended to proceed with the Bill during the present session, its object being mainly to ensure that the first clause of the Pharmacy Act, passed in 1868,—which said there should be regulations for the keeping, dispensing, and selling of poisons,—should be complied with.

On the following Thursday, Mr. Forster moved the second reading, and thereupon Mr. McCullagh Torrens suggested that it should be read *pro forma* and the discussion taken in Committee inasmuch as no one yet knew what the Amendments were.

Although this very reasonable proposal was supported by Mr. Forster himself, it was refused by the House and the second reading was accordingly put off until Monday next.

The principal modification which has been introduced into the Bill is that its operations instead of being confined to Members of the Pharmaceutical Society is extended to all persons who “keep open shop for the retailing, dispensing, and compounding of poisons.” This proviso brings under the operation of the Bill all compounding apothecaries, but does not include general practitioners who make up no medicine except for their own patients. The schedule of the Bill gives the recommendations of the Pharmaceutical Society as to the method of storing poisons, and should it become law the adoption of these recommendations will be compulsory.

### WARREN'S ESSENCE OF RENNET.

HAVING had occasion recently to order rennet whey in the case of a child recovering from gastritis, we took the opportunity of testing, side by side with other similar preparations, Warren's Sweet Essence of Rennet. The observation of its action on milk has satisfied us that it is, of the preparations with which we are acquainted, not only the pleasantest, but the most effective agent for the coagulation of the caseine. It acts, even under unfavourable circumstances of temperature, rapidly and certainly—a quality not enjoyed by all other solutions of the sort, and seldom possessed by the rennet bag itself.

Not having analysed the sweet essence quantitatively, we are unable to pronounce as to the proportion of pepsine it contains. We, however, believe it to be *bona fide* in this respect, and we know it to be effective and reliable as a coagulant.

In the metropolis 2,160 births and 1,328 deaths were registered last week, the former being 53 and the latter 61 below the average. Zymotic or preventible diseases are credited with 409 deaths, of which 235 were from small-pox.

## Medical News.

**Apothecaries' Hall of London.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, the 6th July, 1871:—J. I. Bowes, of Guy's Hospital; H. C. Pope, M.R.C.S., of the Royal School of Medicine, Liverpool; Isaac Willcox, of St. Bartholomew's Hospital; and Ralph Worthington Williams, L.R.C.P. Edin., of the Royal School of Medicine, Manchester. On the same day the following gentlemen passed their primary professional examination:—F. H. H. A. Mahomed, student of Guy's Hospital, and William Edward Webb, student of King's College Hospital, London.

**The Large Mortality of Paris.**—The total number of deaths in Paris, exclusive of those which occurred in the field, during the twenty-five weeks from September, 1870, to February, 1871, was 64,154; and the total for the previous corresponding twenty-five weeks of 1869-70 was 21,978; total 42,176. The highest number was reached in the week ending the 3rd of February, 1871, when the mortality was 4,671, against 980 in the corresponding week of the previous year. The mortality began to diminish from that date, and in the week ending the 3rd March it had fallen to 3,500. Moreover, in the last-named week the deaths from small-pox were the lowest during ten months; the two great causes of death were pneumonia and bronchitis, generally the results of the excessive cold to which the soldiers had been exposed. The fearful suffering in this way is indicated by the terrible fact that in one night more than nine hundred men were reported as frozen to death. The most disquieting fact at the date already mentioned was the prevalence of typhoid fevers. The *Society of Arts Journal* infers that the insufficiency and bad quality of the food, together with the effects of the severe cold and want of fuel, and diseases brought on by fatigue and exposure, caused the death of nearly 40,000 individuals in twenty-five weeks, thus tripling the mortality of the city for that period.

**The Sanitary Condition of Liverpool.**—Drs. Parkes and Sanderson, appointed some time back to conduct certain investigations with regard to the sanitary condition of Liverpool, have forwarded to the local corporation a first instalment of their report upon the subject. The following are the recommendations of the Commissioners:—“1. We recommend that a complete and exhaustive inquiry be made as to the existence of deposits in the sewers, and that in all cases in which such deposits are, in the opinion of the borough engineer, dependent on defective construction, defective inclination, or insufficient supply of water, the works necessary for the remedy of these defects be immediately commenced. 2. In those cases in which the foul condition of the sewers appears to be unavoidable—*e.g.*, in those sewers which are affected by the tide—we recommend ventilation. For this purpose, we think that spacious and lofty shafts afford the only effective means. 3. We do not recommend the adoption of any general system of ventilation, entirely agreeing with your borough engineer in the opinion that for well-constructed sewers of good inclination, with sufficient supply of water, it is unnecessary. 4. We recommend that a complete report be made as to the quantity of waste water discharged into the sewers by manufacturers, with a view, first, to the prevention of its introduction into the sewers in a warm state; and, secondly, to its being, if possible, utilized for surface cleaning and sewer flushing.”

**Testimonial to Mr. Richard Ley, M.R.C.S., J.P., &c.**—This gentleman who retires from a most extensive practice in North Devon, was presented on Thursday last, with a substantial token of the esteem and goodwill of his patients and friends, in the shape of a silver tea and dessert service. The subject of this presentation appears to be held in universal regard, his reception chronicled in the local papers, being given in these simple but telling words:—“Every man, woman, and child appeared to have a smiling face, and they gave their late doctor a most hearty welcome.” Although we do not know Mr. Ley personally, yet, as medical journalists, it gives us great pleasure to record so pleasing a circumstance, one which we heartily desire it were our duty to repeat constantly. Upon presenting the testimonial, the chairman remarked that “they had all known him for a great many years, and he believed there was not one who would not bear testimony to

his zeal and professional acquirements. They had all seen him from day to day labouring to lessen their sufferings, and they could also speak of the great success of his endeavours. During the past year they had been afflicted more than any other district in the neighbourhood with that dreadful scourge typhoid fever, and had it not been for their kind friend how many would now have to mourn the loss of some near relative or neighbour. It was in his opinion mainly due to Mr. Ley that they had got rid of the pestilence, for they all knew how assiduous he had been in attending to the sanitary wants of the parish, as well as the every-day care and attention he had bestowed upon his patients. They could not thank him too much for his kindness, and he felt proud and delighted in handing to him this token of regard.

Seventeen children were poisoned on Friday by eating calabar bean, which had been thrown away as rubbish from a ship in the docks. Medical aid was promptly secured, and the whole of the children appear now to be free from danger.

The health of Paris is good; the death rate continues sensibly to diminish, 872 deaths only having occurred last week against 1,106 in the preceding one.

## Gleanings.

### "Psychology" as a Medical Word.

DR. PETER STEWART writes in the *Detroit Review of Medical Pharmacy* my attention has been arrested by the frequent recurrence of the word "psychology," as used by late American writers, regardless of its meaning, in describing nervous diseases. So often is this the case that the reader is apt to be led to the conclusion that they are all materialists who consider the brain as the soul or mind.

The word is derived from *psyche* (*ψυχή*), breath, soul or spirit, and *logos* (*λογος*), word or thought. Psychology, therefore, means a treatise on the soul or mind. How, then, can it be used in connection with the pathological changes in the nervous system? What meaning can be attached to such terms as the following—viz., psychological medicine, psychological journal, &c., &c.

The time has not yet arrived when this word can be taken out of the domain of metaphysics and placed in that of the positive sciences. A more suitable word than the one now so much in use would be *encephalology*, derived from *en*, in, *kephala*, the head, and *logos*, a word which means a description or treatise on the head or brain, the source of the nerves. Dr. Carpenter, under the word *encephalon*, includes the brain, spinal marrow, and the ganglia of the sympathetic. The extensive signification of this word would intelligently convey any idea we might wish to express in regard to the nervous system.

### The word "Journal."

It is a curious fact that, says Dr. W. H. Lathrop in the *Detroit Review*, although the word "journal" is by derivation synonymous with "daily," it is adopted as a name by more than half the medical journals of this country, no one of which is published daily. The editors, however, will rise to explain that they *write* much oftener than they *publish*—a fact of which delinquent subscribers, to say the least, are certainly made aware. The medical *journal*, while it is published but once a month, may be supposed to present to its readers the news and ideas noted every day.

This same word "journal" is, moreover, the one generally used in speaking of medical periodicals, whatever may be their name, and furnishes an interesting instance of the loss of original meaning which a word may undergo in process of time. We cannot, however, condemn this use of the word. It is entirely sanctioned by the usage of good writers, the ultimate and inexorable law with regard to language.

### Perchloride of Iron and Manganese in Necrosis, Fistulous Sinuses, and Hydrocele.

PROF. MARCACCI states that: 1. Perchloride of iron and manganese, injected into fistulous sinuses, destroys the pyogenic membrane, modifies the state of the walls, and favours cicatrization. 2. In necrosis it acts on the confines of the living bone, stimulating its vessels; so that the detachment

and separation of the dead bone are facilitated by the formation of new vessels in the living. 3. In hydrocele it soon modifies the inner surface of the tunica vaginalis, which becomes filled with plastic exudation, attended with more or less inflammation, according to the quantity and strength of the injection used. 4. It is not necessary that the tunica vaginalis should be distended by the injection, it is sufficient that the liquid be brought in contact with all parts of the membrane. 5. Very little pain is produced by the contact of the solution, but it is not the less efficacious. 6. A weak solution is sufficient, which should be kept in two minutes. 7. In seven cases of hydrocele, in which the injection was used, hard œdema followed, but was not a serious complication.—(*L'Imparziale*).

### The Internal Administration of Chloroform.

DR. G. W. MURDOCK, in the *Journal of Pharmacy*, after alluding to the difficulty physicians have had in finding a good vehicle for the internal administration of chloroform, recommends pure glycerine as one "which answers the purpose so completely as to leave little to be desired." He adds the following suggestions:

"By a little care in rubbing it up, one part of chloroform by bulk can be dissolved in three of glycerine. This solution is perfectly clear, is bland to the taste, and has but a slight odour of chloroform.

"As glycerine is acceptable to almost every stomach, it admits of a wide range of application. It can be taken readily as it is, or can be diluted with water to any extent, without disturbing the solution. Curiously enough, the addition of water immediately increases the smell of chloroform without any precipitation of it. In preparing it, it is best to take one part of chloroform with two parts of glycerine, add the chloroform very slowly, and rub up carefully. Then put it in a bottle, and let it stand twenty-four hours. A little chloroform will have deposited at the bottom. Separate this, and rub it up with the third part of glycerine, then mix it with the rest, and the solution is complete. No further separation will take place. Six ounces of glycerine with two of chloroform will give seven fluid ounces of the solution, so that each fluid drachm contains about seventeen M. of chloroform.

"From the faint odour of the prepared solution I judge that the glycerine protects it almost entirely from evaporation, although some slight loss may occur when preparing it, which it is well to make allowance for."—*Boston Journal Chemistry*.

### Colour-Blindness and its Acquisition through the Abuse of Alcohol and Tobacco.

DR. RICHARD H. DERBY, late Assistant-Surgeon of Prof. Von Graefe, at Berlin, says in the *N. Y. Med. Journal*:

Achromatopsia, akyanopsia (Graefe), anerythroptia, or Daltonism, are but a few of the names that have at various times been applied to colour-blindness.

In the text-books we find cases of this affection cited as literary curiosities. It was believed to be nearly always congenital, and not amenable to treatment.

Modern investigators have immensely enriched this previously barren field. Colour-blindness has been found an almost constant accompaniment of certain diseases of the optic nerve and retina. Excessive use of alcohol and tobacco is now known to produce colour-blindness over a portion or the entire extent of the visual field. Exposure to wet and cold may lead to the same condition.

In many cases of amblyopia, an examination of the perception of colour reveals functional changes most marked, and indeed in many cases, where the ordinary tests would indicate no pronounced difference in the acuteness of vision in various portions of the visual field, we find a most clearly-defined central colour scotoma.

The question may be asked, if colour-blindness is so constant a symptom in certain forms of amblyopia, why is it that patients so rarely complain of it? The explanation is undoubtedly in the fact that "the simultaneous falling off of the acuteness of vision appears to them relatively a far more grievous affection, and a disturbance in their perception of colour seems natural. They are apt too to compare their present amount of vision with what their normal vision was by poor light.

"With deficient illumination at a certain point we lose the power of recognizing, not only the outline, but the colour of objects; we distinguish only light from darkness. Conse-

quently the attention of the patient is only drawn to his colour-blindness in those cases where it is very pronounced, and were, on the other hand, the amplyopia is slight.

"The fact that colour-blindness and amblyopia are not necessarily associated together is reason enough that the condition of the perception of colour should be especially examined in affections of the eye; such an examination may reveal us facts striking and unexpected, of importance for our diagnosis and prognosis."

NOTICES TO CORRESPONDENTS.

Dr. WOODWARD, Worcester.—The gentleman referred to has not again put himself in communication with us concerning the threatened action for libel. Truth is sometimes found to be a bitter pill to swallow, and as we stated nothing but what was strictly in accordance therewith, and refused to retract even with an "Action for Libel" hanging over our Proprietorial and Editorial heads, we presume and hope our friend was better advised than to immortalize himself and us in Court.

Mr. W. D. M., Glamorgan.—We will do all we possibly can, and will communicate by letter when an opportunity occurs in the direction you name.

A LAY-READER writes to ask us "kindly to give the address of some distinguished medical man who has made diseases of the nose his special study, or quote the name of any book on the subject." We confess ourselves unequal to the task; can any of our friends help us?

Dr. ALEXANDER LANE.—Your communication "On Fevers" received just as we were going to press. Will attend to your request if not accepted for our columns.

Mr. H. SEWELL.—The pamphlet was received and acknowledged in the usual way in our number for June 28th.

Dr. ARTHUR.—At the moment of going to press, the proof of Lecture 5 had not arrived.

The following communications are in type, and will appear, if possible, in our next:

- Dr. Letheby, "On the Purification of Water." (2nd part).
Dr. Athhill, Lecture 5, "On Diseases Peculiar to Women."
J. C. Dickinson, "On Indian Splice."
R. Uniacke Ronayne, "On the causes and cure of Prostatic Stricture."
J. L. Milton, "On the Treatment of Eczema."

PERHAPS we may be excused the journalistic vanity involved in the publication of the following note:

To the Editor of "The Medical Press and Circular."

DEAR SIR,—I enclose my subscription for the last year, I am now a subscriber for thirty-one years, and I am not tired of your paper.

Yours, very faithfully, A. D. W.

July 3rd, 1871.

Case of "Syphilitic Iritis attacking both Eyes in succession;" treated principally by use of turpentine and blisters. By J. Smith Chartres, M.A., M.D., Surgeon 8th Hussars. Accepted.

POOR-LAW REFORM.

To the Editor of "The Medical Press and Circular."

SIR,—Allow me to request all interested in Poor-law reform, to write to their Representatives in Parliament, asking them to attend the House on Friday next, July 21st. If they know that Mr. Corrance will press for a division, (if necessary), I believe there will be a full house. Now is the time for the "long pull."

Your obedient servant,

W. W.

VACANCIES.

- Infirmary for Epilepsy, Portman square, W. Physician. (See advt).
General Hospital for Sick Children, Manchester. Resident Medical Officer. Salary £100, with board. (See advt).
Lancaster County Asylum. Assistant Medical Officer. Increasing salary, commencing £100, with board and residence.
West London Hospital. Junior Physician. Honorary.
Farringdon Infirmary. Medical Officer. Salary £126, with extras.
Middlesex Hospital. Lectureship on Physiology.
St. George's Hospital, London. Teacher of Physiological Chemistry.
Orthopaedic Hospital, London. House-Surgeon. Salary £100 per annum.

APPOINTMENTS.

- BAKKE, W. M., F.R.C.S.E., Assistant-Surgeon to St. Bartholomew's Hospital.
BLOXAM, J. A., F.R.C.S., Junior Surgeon to the West London Hospitals.
CHAMBERS, W., M.D., Medical Officer for the Sherecock Dispensary District of the Balficborough Union, Co. Cavan; and Medical Attendant to the Royal Irish Constabulary, Sherecock.
CULLINAN, M., M.D., Medical Officer for the Quin Dispensary District of the Tulla Union, Co. Clare.
CURTIS, J. G., jun., L.R.C.P. Ed., L.R.C.S.I., has been transferred from No. 2. to No. 1. Cork Dispensary District of the Cork Union.
DICKINSON, J. C., M.R.C.S., Surgeon to St. Marylebone General Dispensary.
DONOVAN, J. D., L.R.C.P. Ed., Medical Officer, &c., for the South-West Division of the Cork Dispensary District of the Cork Union.
HOLMES, W. H., L.R.C.P. Ed., L.R.C.S. Ed., has been transferred from No. 7 to No. 2. Cork Dispensary District of the Cork Union.
JONES, T., M.B., Physician to the Brecon County Infirmary.
O'BRIEN, R. R., M.D., Medical Officer, Public Vaccinator, &c., of the Bansha Dispensary District of the Tipperary Union.
PRESTON, E. P., L.R.C.S.I., L.R.C.Q.C.P.I., L.M., Medical Officer to Kilkel Workhouse, Co. Down, Medical Attendant to 1 Royal Irish Constabulary, Kilkel, and Medical Officer to Kilkel No. 1. Dispensary District.

Marriages.

- EVERS—CARVER.—On the 29th ult., at Holy Trinity Church, Brompton, Benj. EVERS, Esq., of the Bengal M.S., to Emma, second daughter of Mr. James Frederick Carver, of Brompton, London.
MANSER—BAILY.—On the 5th inst., at St. John's Church, Blackheath, Frederick Manser, M.R.C.S., of Tunbridge Wells, to Jane Maria, eldest daughter of Thomas Peter Bailey, Esq., of Blackheath.
KLAMBOROWSKI—SMITH.—On the 29th ult., at Clare, Suffolk, the Rev. L. Klamborowski, Curate of Tilbury, to Frances Elizabeth, youngest daughter of R. T. Smith, F.R.C.S., of Clare, Suffolk.

Deaths.

- LEAHY.—On the 3rd inst., at Southsea, J. W. Leahy, L.R.C.S.I., R.N.
LONEY.—On the 3rd inst., at Duke street, Macclesfield, William Loney, M.R.C.S.E., aged 59.
PEACOCKE.—On the 5th inst., at Hazareabagh, India, George Peacocke, A.M., T.C.D., M.D., Surgeon to Her Majesty's 63rd Regiment. (By Telegraph).

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sal es and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Table with 2 columns: Description of advertisement type and Price. Includes Seven lines and under, Per line afterwards, One quarter page, Half-page, and One do.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, BRIDGE STREET, MANCHESTER.

The Office of RESIDENT MEDICAL OFFICER to the above Institution will become vacant on August 14th. Candidates for the Office must be on the "Medical Register" and unmarried. The salary is £100 per annum and board. Applications addressed to the Hospital, Bridge Street, must be sent up to July 22nd.

INFIRMARY FOR EPILEPSY AND PARALYSIS, CHARLES STREET, PORTMAN SQUARE, W.

A VACANCY having occurred in the Medical Staff of the Infirmary through the resignation of Dr. John Harley, Candidates for the PHYSICIANSHIP are requested to send in their applications on or before Monday, July 31st. They must be Members or Fellows of the Royal College of Physicians of London.

By Order of the Committee,

July 1, 1871.

EDWARD WATHERSTON, Hon. Sec.

CHURCH STRETTON PRIVATE ASYLUMS

FOR the UPPER and MIDDLE CLASSES of BOTH SEXES, are situated among the Shropshire Hills, Twelve Miles from Shrewsbury, on the rail to Hereford

Apply to (Wm. Hyslop Esq., Stretton House, for Gentle-men; Mrs. BAKEWELL, the Grove, for Ladies.) Church Stretton, Shropshire.

Wide page 1016 in the Medical Directories for 1867.

PRIVATE RETREAT

FOR

THE UPPER AND MIDDLE CLASSES

OF BOTH SEXES, MENTALLY AFFLICTED,

TUE BROOK VILLA,

NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWEN. Vide page 1075, "Medical Directory," 1869.

MALVERN COLLEGE.

The THIRD TERM will begin on Wednesday, September 20th. Terms of Tuition and Board, £90 per annum. For Clergymen's Sons after Examination, £80. Three Scholarships worth £80 per annum for one or for two years to be examined for in December. For details apply to the Secretary.

JAMES'S FEVER POWDER.

4s. 6d. PER BOTTLE, PACKETS 2s. 9d. EACH.

PREPARED and sold by J. L. KIDDLE, 31 Hunterstreet, Brunswick square, London.

This preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remarks on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists

ESTABLISHED 1848. PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE

50 Lincoln's-inn fields, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c., (King's Coll.), and Author of VIA MEDICA, has always upon his books a large number of desirable investments and available Appointments for negotiation.

Dr. Langley devotes his prompt personal attention to the negotiations entrusted to him, which are treated with the most scrupulous reserve.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers. Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2. LOCUM TENENS.—Dr. Langley has now organised a thoroughly reliable Staff of Suitable Gentlemen to take full Charge of any Practice which may require it in the absence of the principal, at fees from £2 2s. upwards, according to age, experience, qualifications, &c.

PRACTICES AND PARTNERSHIPS NOW OPEN for negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on receipt of two stamps) as below:—

Y 235. DEVONSHIRE, near the Sea.—The Practice is old established, and situate in the most beautiful part of the County; receipts average £400 a year, including an easily-worked Parish appointment realising £100 a year. There is no opposition within three miles. There is a choice of two houses, pleasantly situated, for the successor, to whom an efficient introduction can be given from a suitable successor.

Y 234. LONDON.—In a large thoroughfare, an old established Practice, with open Surgery. Gross receipts average about £450 a year, of which a considerable amount is taken in cash, although this department has not been pushed. The house contains eight convenient rooms, at a moderate rent. The whole connection can be safely transferred and largely increased by an active gentleman.

Y 233. COUNTRY PRACTICE, within easy access of the Metropolis. The present income is about £450; but for several years the Practice has not been actively pushed. Appointments yield £190 a year. There is a population of 4,000 in the town, and only one opponent; the patients are of a good liberal class. The house contains twelve rooms, with stabling, garden, and paddock. There is very little night work, and no assistant is necessary. Midwifery fees £1 1s., and upwards. A thoroughly efficient introduction would be given, and as an investment, the Practice offers an unusual opening for a gentleman commencing on his own account.

Y 232. LONDON.—A large and old established Practice for Transfer, under conditions affording the highest guarantees of good faith, as the vendor is retiring in consequence of serious and sudden illness. The books show that upwards of £435 were taken in ready money fees during last year, and that more than £700 were booked; the previous years show a much higher average, and very few bad debts. Midwifery fees, at £1 1s. and upwards, yielded £140. Public Appointment £550 a year. The residence is extremely convenient, situate in a principle thoroughfare, with garden at the back, and stabling. Rent £50 a year. There is a detached Surgery, where the Assistant resides. The introduction to the Practice may be by Partnership or otherwise.

Y 231. Practice and Mansion for Sals, with seventeen acres of land. The Practice has not been actively pushed, and could be greatly increased, the average receipts at present being about £400 a year. To a gentleman seeking a pleasant country life, with light professional occupation, the investment is especially suitable. The house itself is a noble mansion, standing in its own grounds, which are beautifully laid out, with stabling, farm-buildings, and everything complete.

Y 228. PARTNERSHIP, in a large town. There is an opening for an eligible successor to a share in a good Non-dispensing Practice, in the Midland Counties. All Clubs, contracts, and Union appointments have been declined. There are about twenty cases of Midwifery yearly, at fees from £2 2s. to £5 5s. The Practice lies within a narrow area, and is conducted one-half. No assistant required. The incoming partner, if unmarried, could at first reside with the senior if desired. The population of the town is about 40,000, and the present incumbent is Honorary Surgeon to the local Hospital. A third share is offered with succession at half, at a period to be agreed upon. The receipts average £900 a year, but could be doubled by the co-operation of a suitable gentleman.

Y 226. In a picturesque locality a Surgeon compelled by ill-health to retire, desires to secure a suitable successor. The practice realises between £600 and £700 a year, and is believed to be wholly transferable. Fees good and few bad debts. The successor may occupy the residence of the present incumbent or suitable lodgings. The expenses of conducting the practice are small, and the opening is peculiarly suitable for a gentleman of limited capital and of active habits. To secure a suitable successor the vendor is willing to accept a premium of £400 on which a part may be paid by instalments.

MEDICAL ASSISTANTS.

VIA MEDICA.—“Essential to every Principal, Assistant, and Student.” Post free, 3s. 3d.

Dr. Langley's Quarterly List of Selecting PRACTICES and PARTNERSHIPS for JULY is now ready. Post Free on application.]

NOTICE.—BEST QUALITY ONLY.—SAMPLES FREE.

ISLINGTON GLASS BOTTLE COMPANY WORKS.

Established nearly hundred years.

FOR Varicose Veins and Weakness

SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, pervious, light in texture, and INEXPENSIVE, yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise, a strong low-priced article for Hospitals and the Working Classes.

ABDOMINAL SUPPORTING BELTS, those for Ladies' use, before and after accouchment, are admirably adapted for giving adequate support with EXTREME LIGHTNESS—a point hitherto little attended to

Instructions for measurement and prices on application, and the articles sent by post from the Manufacturers.

POPE and PLANTE,

WATERLOO-PLACE, PALL-MALL, LONDON.

The Profession, Trade, and Hospitals Supplied

RUPTURES. BY ROYAL LETTERS PATENT.

WHITE'S MOC-MAIN LEVER TRUSS

Is allowed by upwards of 500 Medical gentlemen to be the most effective invention in the curative treatment of Hernia.

The use of a steel spring, so often hurtful in its effects, is here avoided; a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Single Truss, 16s., 21s., 26s. 6d., and 31s. 6d. Postage, 1s.

Double Truss, 31s. 6d., 42s., and 52s. 6d. Postage, 1s. 8d.

Unibalsic Truss, 42s. and 52s. 6d. Postage, 1s. 10d.

NEW PATENT

ELASTIC STOCKINGS KNEE-CAPS, &c

for Varicose Veins, Weakness, and Swelling of the Legs, &c.

Prices 4s. 6d., 7s. 6d., 10s., and 16s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER, 228 Piccadilly, London.

The usual discount to the Profession.

MR. P. BOURJEAUD,

'begs to inform

THE MEDICAL PROFESSION THAT HE INTENDS PERSONALLY TO SUPERINTEND THE ENTIRE MANAGEMENT OF HIS LONDON ESTABLISHMENT,

and requests that all orders may be sent to

49 DAVIES STREET,

BERKELEY SQUARE, LONDON, W.

CAUTION.—Mr. BOURJEAUD respectfully cautions the Profession against advertisers who have assumed his inventions.

### ON INDIAN SPLEEN.

BY JAMES C. DICKINSON.

Surgeon to the St. Mary-le-bone General Dispensary.  
Late Her Majesty's Bengal Medical Staff.

*Introductory Remarks.*—Indian practitioners can hardly fail to be struck with the little that is known respecting Spleen and its diseases in England; due probably to its comparative infrequency in this country. In India, on the other hand, Spleen is a disease daily met with, most of its pathological conditions are understood, and there are many well known remedies, if not actually specifics, for its affections. Indeed, so common is the affection in Hindostan and elsewhere, that Indian practitioners when treating natives for any complaints, invariably ask them if they have "Pilli," i.e., spleen disease; and Dutrolau well observes that "among the organic changes intimately connected with paludal fever, those of spleen more especially present themselves for notice, and are the most frequent, characteristic, and marked."

Again, it may be inferred how rare spleen disease in England is, or at least has a tendency to end fatally from the fact that the Museum of the College of Surgeons contains few pathological specimens. In Dr. Crisp's collection there is, if I remember rightly, only one specimen of enlarged spleen.

So prevalent is "spleen" throughout India that not only the "Baidis and Itakcems" (native practitioners and empirics) have, or pretend to have, a specific; but in almost every native village a reputed simple is known for its cure. Among the Eurasians also, as well as the European settlers, as Indigo and tea planters, remedies are prescribed, the composition of which is made a great secret of.

Most Indian writers speak of "spleen" as the result of intermittent fever. Few writers regard spleen as a disease *per se*. This omission, or recognition, as we shall hereafter find, is somewhat remarkable, as reasons or proofs will be given to show that not only does the condition of the spleen undergo abnormal changes, but that these changes take place without any symptoms of fever occurring or preceding them.

Again, we shall see that the tendency of this organ to become affected is commonest among the Natives, secondly among the Eurasians and Country-born, and least of all

among Europeans, though it is especially common in the children of Europeans born in India.

"Spleen" has also obtained an unenviable notoriety on account of its being a frequent cause of death. "Death from ruptured spleen," the result of a fall or slight blow, figures largely among the returns of accidental death in most parts of India, and in bygone days when striking native servants was a practice, which, unhappily, prevailed to some extent, newly-arrived Europeans were particularly cautioned never to strike their servants on the body.

On this point of Indian Medical jurisprudence I would refer my readers to Dr. Norman Chever's valuable manual on the subject. In a paper purporting to offer a certain amount of practical instruction on "spleen" it will not be necessary to occupy space by describing the symptoms or varieties of intermittent fever, or the abnormal sounds of the heart owing to enlargement of the organ. The various text-books well describe the forms of intermittent fever, and in Dr. Morehead's work a series of cases are given of abnormal precordial dullness alone existing or associated with systolic murmur resulting from enlargement of the spleen.

It will be sufficient to state here that intermittent fever, is associated with spleen, while my own observations lead me to regard *Quotidian* as the type of fever most commonly associated with enlarged spleen among Europeans, and that this form of fever prevails most extensively in the months of October and November.

Among the Natives the Tertian variety is the type I have generally noticed in conjunction with enlargement of this viscus—not that this type is the one which showed itself in the first attacks of fever—but I incline to the opinion of Morehead that the tertian type is one occurring in individuals who have suffered on previous occasions and in whom the fresh attack is often traceable to ordinary and recently applied exciting causes, and that the occurrence of this type may generally be regarded not as the evidence of the recent introduction of malaria into the system, but as that of a pre-existing abiding influence, sometimes dormant, but now re-excited into action by an ordinary cause.

There are two forms of spleen disease met with in India—simple engorgement or hyperæmia and chronic engorgement, which is the true "leucocythæmia splenicæ."

The first—"simple engorgement"—is the form so commonly noticed among newly-arrived Europeans, and from my own observations, which were made during the cold seasons while the mutiny lasted, I noticed that the Euro-

pean soldiers and sailors were attacked with fever associated with spleen, some recovered and afterwards enjoyed greater immunity from future ailments. *Per contra*, I have observed that among new arrivals those who are first attacked with remittent fever, and subsequent congestion of the liver, it is quite possible to predict with something like certainty that the process of acclimatization—whatever that may be—will be tardy and difficult, or that the tendency to recur of both the fever and hepatic congestion is so marked, that nothing short of a voyage to England can be considered curative.

Intermittent fever associated with spleen for the reason above given, I have regarded as constituting a part of what is understood as the acclimatizing process, not so, however, those who have contracted intermittent fever which is followed by dysentery. While on this point I may notice that I observed, while in India, that both men and officers who had served with their regiments in the Crimea enjoyed better health and were less susceptible of malarial and other influences than those men who came direct from England, while those men who had served in cold climates such as Canada, were very subject to glandular affections, more especially of the neck and groin.

The other and commoner condition of the organ—leucothæmia splenica is that which is peculiar to Natives. Instances of the same condition I am about to speak of are to be occasionally met with both among Europeans and Eurasians who have long resided in localities notoriously unhealthy.

The symptoms of leucothæmia splenica are pain, tenderness, fulness or weight in the left hypochondrium, and increase of volume. The exact enlargement of the spleen is ascertained by percussion or very frequently from its enormous size it may be seen as a large abdominal tumour reaching to the crest of the ilium, and inwards beyond the mesial line, a dingy appearance of the conjunctiva, a sallow, lurid, or partially anæmic appearance of the skin, sympathetic pains of various kinds, impaired digestion, tongue pale, flabby, and indented at the edges, palpitation, shortness of breath, tinnitus aurium, general feeling of *malaise*, frequent spermatorrhœa, albuminous urine, oxalate of lime, crystals or sugar in that secretion. In natives, as a rule, fever as a primary affection less frequently comes under observation in connection with enlargement of this viscus.

Among the Europeans and Eurasians the symptoms, as a rule, are not so strongly marked, and intermittent fever sets in prior to the engorgement of the spleen. The spleen rarely, however, attains the enormous size it does among the Natives, and even where there is extreme debility the recovery is singularly rapid. The type of fever, as has been before noticed, among Europeans is—the Quotidian—among the Natives the Tertian.

The temperature generally varies from 98 degs. F. in the morning to 101 degs. F. in the evening. On examining the blood we shall generally find there is an enormous increase of the white corpuscles equal to the red in number, while in some exceptionally scarce cases I have fancied the white corpuscles to be considerably in excess of the red, and most writers agree that the *size* of the white corpuscles is twice as large as the ordinary.

The history of leucothæmia splenica is very obscure, and this enlarged condition of the organ comes on so insidiously, especially in the Natives, that it is difficult to fix the date of its first appearance.

This condition, I think, may be regarded among Europeans as the result of a long residence in the tropics, combined with exposure to heat and malaria, inducing frequent attacks of intermittent fever and establishing that condition of the system known as *cachexia loci* which may be defined as meaning a peculiar anæmic condition resulting from long exposure to the influences of noxious or malarial climates.

*Treatment.*—In simple cases of ague cake or congestion of the spleen, arising from intermittent fever, the ordinary treatment suffices, by a saline aperient, and subsequently quinine and iron, with generous diet and malt liquor.

In my own practice I have never obtained very marked advantage from the employment of large doses of quinine—on this subject my readers are referred to my remarks on quinine in the chapter on fevers. When, however, the spleen is hypertrophied as the result of *cachexia loci*, the following remedies will occasionally succeed in restoring this viscus to its ordinary normal condition—viz.: sulphate of bebeerine, muriate of narcotine, chiretta, and atees. None of these, however, can be regarded as specifics. The remedy which I have prescribed in some hundreds of cases with marked success is a native medicine called “bindaäl or bindaul, the *Luffia echinata*, nat. ord. *cucurbitaceæ*.” A full description of the plant, together with its mode of administration was given by me in the second vol. of the *Indian Medical Gazette*.\* The official part of the plant is the stalk made into an infusion—strength two drachms to the pint of boiling water.

The general treatment includes the prevention of the paroxysm—to endeavour to remove the cachectic condition, avoid all measures which are calculated to increase asthenia, or still further to deteriorate the blood, and above all, to restore the spleen to its normal healthy condition, for so long as the enlarged spleen exists, so certain are patients liable to returns of the fever, and *pari passu*, with each fresh attack they become weaker and ultimately die. Quinine, lactate of iron, chiretta, and sulpho-carbolate of iron, will be found the most valuable medicines to employ after the bindaäl has removed the engorged condition of the spleen.

Food of a nutritious and easily assimilable character, together with attention to the excretions.

Iodine and bromine I have found too depressing, and for some years past have ceased to prescribe them, although I am aware many distinguished practitioners in England do so. The condition, however, of patients in England so affected cannot be classed in the same category with those who have been exposed for years to a tropical climate and malarial poisons. Mercury is totally inadmissible in diseases of the spleen, *the smallest dose will induce most violent salivation*. In illustration of this peculiarity, I may mention the case of a native Sepoy, who I treated when in charge of the Erinpoora Irregular Force. The man came into hospital with syphilis, and it never occurred to me at the time to examine the spleen, I ordered him small doses of grey powder with quinine. The next day on visiting the hospital, I found the man suffering from profuse salivation, although he had only taken six grains of grey powder. From this error in practice, I never forgot the maxim of *always before administering mercury to a native to ascertain the condition of the spleen*.

As regards the hygienic treatment, the hot and malarious seasons should be avoided (speaking of the Bengal Presidency) from the beginning of March to the middle of November: visiting the various hill *sanitoria* of *Darjeeling*, *Missouri*, *Chukrata*, and *Simla*; but, above all, a sea voyage and a prolonged residence in Europe. Europeans proceeding home should so calculate the time as to arrive in England in the summer, and thus avoid the particular seasons of Europe and Asia inimical to the Anglo-Indian invalid.

Among the Natives we must be satisfied to know that in Bindaäl, we have an almost specific remedy, and that when the normal condition of the organ is restored, we must build up and fortify the constitution against future attacks, by the administration of tonics, among which iron holds the first place, and to endeavour without interfering with the prejudices of the natives to inculcate the first elements of hygiene.

*Pathology.*—This is essentially congestion of the spleen, and if we remember the causes which bring about this condition, what constitutes *cachexia loci*, together with the minute structure of the organ, the vagueness of our knowledge will be less manifest than might at first appear.

\* Vide *Indian Medical Gazette*—Dr. Kanny Loll Dey's work on “The Indigenous Drugs of India,” and “Indian Pharmacopœia.”

First, We have simple engorgement of the spleen ; where the gorged state of the vessels of the liver impede the passage of the blood through the splenic vein as mentioned by Dr. G. Budd. In many cases of dyspepsia that I treated in India, I noticed as a very frequent symptom, pain in the left side after eating which was doubtless due to this cause.

This simple congestion or engorgement it is that we find so common in cases of intermittent fever among Europeans, both adults and children. In these cases it is most probable that the blood is uncontaminated. The season when this condition prevails most is at the termination of the periodic rains, when the nights become comparatively cool or cold after hot days.

The second condition "compound congestion," is the commonest variety met in India. Here we have the organ kept in a state of passive congestion, while the debility that co-exists, renders the patient unable to resist the alternations of temperature. The circulation is determined from the surface and extremities upon the internal viscera. The organ is kept in a passive state of congestion, and the longer the vessels are kept distended, and the more yielding the surrounding tissues, the greater, of course, will be the enlargement. This unnatural fullness of the capillary vessels must ultimately interfere with the proper working of the spleen, whatever its use may be, and this condition, "compound congestion," it is that produces the symptoms I have described.

Leucocythæmia splenica is the resultant, therefore, of repeated congestions of the spleen, brought on either by mechanical causes, such as sudden cold, whereby the circulation is determined from the surface and extremities upon the internal viscera, or from the frequent recurrence of the cold stage of either intermittent or remittent fever, or that the presence of the malarial poison in the system produces this abnormal condition of the organ. When it is borne in mind that the history of the majority of cases of leucocythæmia splenica give pretty nearly all the indications or characters common to blood diseases, I think my readers will be disposed to agree with me in attributing most of the phenomena of this ailment to the paludal poison, rather than to the mechanical effect of cold.

Let me, by way of illustration quote the late Dr. Todd on this point : "The morbid element may have been introduced into the blood as a poison, which speedily deranges the normal changes which are continually going on within. In this way, all contagious diseases are propagated, the matter of contagion having been introduced into the blood ; malarious diseases are also referable to this cause." And again, "All true blood diseases, whatever their primitive cause may be, exhibit certain characters in common. In all of them, we find a greater or less degree of febrile disturbance at an early stage, and this is frequently preceded by a stage of depression and of rigor. Pains in the limbs or in the joints, sometimes attended with swelling of the latter, and inability to move them freely, in consequence of effusions into them, are very commonly met with. The cutaneous function is more or less disturbed, and this disturbance manifests itself either in a harsh, dry, and burning hot skin, or in a profuse perspiration, sometimes exhaling a disagreeable sour odour, or in a cutaneous eruption belonging to one of the multifarious forms which those diseases are prone to assume. The secretions of the liver and kidney often appear unnatural, the former being too great in quantity or altered in quality ; the latter frequently rather diminished than increased, of a high colour, and depositing a brick-dust sediment in greater or less quantity. In some instances internal organs do not escape, but become the seat of an irritation which may entail very serious consequences. Those morbid matters which are introduced from without, and even some of those primarily generated in the blood, are very prone to fix themselves upon particular parts to the exclusion of others, and sometimes the life of the patient is endangered by the

destructive influence of such poisonous matter upon the affected organs. As soon as the morbid matter has been eliminated from the system, these symptoms subside, and the organs affected resume their natural state."

Morehead in speaking of simple enlargement of the spleen, says, "The blood is determined from the surface to internal parts, and is liable to accumulate in such venous arrangements as those of the spleen and portal system of the liver, and when stagnating in the splenic capillaries its transfer in undue quantities into the pulpy parenchyma of the organ readily takes place. Under recurrences of the cold stage, these events are repeated, and the bulk of the spleen necessarily increases."

With reference to the changes of structure which take place, we must regard them as consequent upon the hypertrophy. Density of the organ will partly depend upon the quality and quantity of the blood present in the vascular system of the organ, and partly on the increase and condition of the parenchymatous pulp, as any of the fibrinous or albuminous constituent has become converted into tissues of low organisation. When this metamorphosis of the fibrine or albumen into tissue takes place, then some degrees of enlargement will become permanent. *Per contra*, excess of blood in the vessels or organised pulp organ may be restored to its normal condition.

In autopsies, we generally find the increased size of the organ due to a condition of hypertrophy with induration, or perhaps it would be more correct to say hypertrophy with brittleness. The trabeculæ are increased in number and thickness, and the venous sinuses diminished in number. The splenic corpuscles are granular and larger than natural ; section of the organ is smooth, has a mottled appearance, and as a rule, is easily broken down by pressure with the thumb, though an opposite condition sometimes exists.

The majority of the cases of enlarged spleen that have come under my notice among Natives, I have not considered as being the commencement, nor the seat of the febrile phenomena, but have attributed them to *cachæxia loci*, the resultant of malaria. A similar condition of the liver is brought about in Europeans from a precisely similar cause *cachæxia loci*. This view of leucocythæmia splenica is opposed to the views of many able writers. Morehead is very clear on this point—he says : "But when it is recollected that enlargement of the spleen and concomitant *cachæxia* may take place from the influence of malaria without the intervention of fever, then the belief must be entertained that malaria exercises a primary deteriorating influence on the blood, and that the altered state thus induced favours stagnation, and in some circumstances is the chief, if not the proximate cause."

Spleen in women, especially Natives, is frequently associated with suppressed menstruation, or leucorrhœa. Children, especially Europeans, seldom permanently or completely recover, unless they take a sea voyage, or are sent to England. The association of spleen with hepatic disease, will be noticed in the chapter "On Diseases of the Liver."

## CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians ; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE V.

*Menorrhagia—Definition—Causes—Constitutional—Local—Sabinvolution—Treatment—of—Uterine porte causative—Plugging vagina—Medical treatment.*

I propose to day gentlemen to draw your attention to the subject of menorrhagia, it is of the greatest importance

both on account of the frequency of its occurrence and of the serious consequences which follow it.

The term "Menorrhagia" strictly speaking means profuse menstruation, the ordinary menstrual period being prolonged, or the quantity of blood lost during the menstrual period of average duration, being an excess of what is normal. In general both these conditions are present, the period being prolonged and the quantity of blood lost being excessive—but we not unfrequently meet with cases in which a discharge of blood takes place from the uterus during the interval between the menstrual periods, to such attacks of hæmorrhage, the term metrorrhagia is by some applied. Let me first of all impress on you that menorrhagia is not a disease, it is only a symptom of a diseased condition, whether it be that of the system at large, or of the organs of generation only. It is therefore incumbent on you, in dealing with every case of menorrhagia which may come under your observation to endeavour to determine before you attempt to treat it, on what the symptom depends. I know of no affection in the treatment of which professional character is so frequently lost from want of due care in attending to this important point.

Now the causes on which menorrhagia may depend are twofold, constitutional and local. I shall speak briefly of the former class first, and subsequently enter at length into the consideration of the latter as those which are more immediately within the province of the obstetric physician. The general constitutional causes which predispose to menorrhagia are not very numerous, nor is their influence very distinctly marked. The following are the most common:—

(1.) Debility arising from any cause, but more especially if the result of prolonged lactation is I think that to which it is most frequently due. In such cases menorrhagia often assumes a very aggravated form, thus a delicate woman continues to nurse, although menstruation has reappeared, and the patient thus weakened by the double drain, rapidly loses health and strength.

(2.) Again profuse menstruation is seen in young women of full habit, but sympathetic temperament, I have met with several well-marked instances of this; in one especially the tendency to menorrhagia is so great and so difficult to restrain that on more than one occasion I feared, as a last resource, I should be compelled to plug the vagina, this patient is quite a young girl and looks the picture of health. In her case the only remedy which seemed to exert any decided influence in checking the great loss is the application of hot water bags to the spine, as recommended by Dr. Chapman. A mode of treatment well worthy of a trial.

(3.) Again as age advances, and the climacteric period of life approaches women are liable to menorrhagia sometimes of a very aggravated character; not unfrequently some months elapse without the normal discharge appearing, and then it comes on so profusely as to give rise to the suspicion that pregnancy had existed, and had terminated by abortion. The same train of symptoms is not very unfrequently met with in recently married women; from the non-appearance of the catamenia at the regular period, they naturally believe themselves pregnant, till after the lapse of some weeks they are unpleasantly undeceived by the return of menstruation in an aggravated form—in both cases the cause is probably the same—namely, temporary congestion of the uterus, and probably of the ovaries.

(4.) Disease of the heart is sometimes attended by menorrhagia, this evidently depends on congestion; the results of the retardation of the return of the blood to the right side of the heart and occasionally the loss of blood in these cases seems to give temporary relief. A good example of menorrhagia depending on this cause, was seen in the case of a woman long under observation in this hospital, who for years laboured under mitral obstruction, and in whom the attacks of profuse menstruation sometimes assumed an alarming aspect.

(5.) Analogous in nature to these are cases which depend on chronic hepatic disease or hepatic congestion. However as mentioned in another lecture, hepatic congestion may cause a diminution rather than an increased flow of the menstrual discharge.

(6.) Menstruation too is met in connection with that form of renal mischief known as Bright's disease; but the cause then is different for it is not due to congestion but to the fact of the blood being in this disease deprived of its albumen, and consequently in a condition favourable to exudation through the walls of the capillaries, but all these affections fall within the province of the regular, rather than of the obstetric physician, and therefore I must leave you to learn from my colleagues the mode in which menorrhagia depending on these causes should be treated.

The local conditions causing profuse menstruation are numerous and very important—they are:

1. Subinvolution of the uterus.
2. Granular ulceration of the os and cervix uteri.
3. Inflammation and congestion of the membrane lining the cavity of the uterus, and a granular condition of that membrane.
4. Retention within the uterus of a portion of placenta or of the foetal membranes.
5. Polypus of the uterus.
6. Fibrous tumours of the uterus.
7. Inversion of the uterus.
8. Ovarian excitement or congestion.

This is a long list, and yet the lesions enumerated in it are all, with the exception of inversion of frequent occurrence, and all frequently cause menorrhagia.

Subinvolution of the uterus is a far more common cause of menorrhagia than is generally supposed; indeed in married women or in those who have been at any time pregnant; profuse menstruation is probably more frequently dependent on this condition than on any other. To this list I think we should add cancer; some authors no doubt object to it being considered a cause of profuse menstruation and in the majority of the cases of this terrible disease, the discharge to which sooner or later gives origin, is not in any way connected with menstruation, and therefore to term it menorrhagia is incorrect, but in others, especially in cases of epithelioma, menstruation is augmented and the term is then correctly applied; I think therefore that it is better to speak of cancer as a possible cause of menorrhagia. I must now proceed to call your attention to each of these conditions somewhat more in detail.

When we speak of subinvolution of the uterus we mean that the process by which the womb regains its original size subsequent to delivery or abortion has been from some cause retarded or arrested, this process has been termed involution, and when it is incomplete we talk of the uterus as being in a condition of imperfect involution or more commonly subinvolution, this process should be completed within a few weeks from the date of delivery. It is one of the most remarkable phenomena which occur in the human body. The uterus immediately before the expulsion of the fœtus measures about fourteen inches in length and weighs twenty-five ounces, and often even more. Immediately after delivery its size is reduced to considerably less than one half its former bulk, its weight also is proportionately diminished, while if the process proceed regularly and unchecked by any cause the womb will after the lapse of five or six weeks measure about three inches in length, and weigh but two ounces. The first step in this process is that both the supply of blood to the uterus is checked, and the circulation of blood through that organ interrupted by the contractions of the muscular fibres of the uterus, a process which commences the moment labour terminates, and goes on in a more or less painless manner for some days subsequently; while at the same time fatty degeneration and disintegration of tissue on the one hand and absorption on the other, rapidly complete the work of reducing the uterus to its normal size and restoring its compactness of tissue.

But you can easily understand that numerous causes may interrupt this process, thus in weakly debilitated women the uterine contractions may not be sufficiently powerful to check the augmented blood supply and consequently the nutrition of the organ may continue almost as active as previous to delivery, and consequently the uterus will remain in a state which may be considered as one of permanent hypertrophy. Instances of this are very numerous. An exactly similar condition may be brought about in healthy muscular women if they leave the recumbent posture too soon after delivery, and as many especially in the lower orders, do return to their ordinary occupations long before the uterus has regained its normal size. Again pelvic inflammation in any of its varieties is a common cause interrupting and often arresting the involution of the uterus. Subinvolution also may follow on abortion, even when it occurs in the early months of pregnancy, a fact you should not overlook—but from whatever cause occurring subinvolution soon gives rise to very troublesome and distressing symptoms, of which menorrhagia is the most prominent and alarming, the one too for the relief of which we are most frequently consulted. I cannot better exemplify this affection than by calling your attention to the case of C—D—, who is still in hospital she is aged forty-three, has had six children, and has never enjoyed good health since the birth of the last ten years ago; shortly after which she noticed that menstruation was much more profuse than formerly, for a long time back each period has lasted for not less than ten or twelve days returning after an interval of only a fortnight. On admission she complained of debility of great pain in her back of irritability of the bladder and consequent straining and tenesmus, she also suffered from profuse leucorrhœa. The effects of this long continued drain was manifest in her appearance, you must have remarked how perfectly ex-sanguine she was. I expressed the opinion from the history of the case, dating as it did from immediately after labour, that the menorrhagia would probably be found to depend on subinvolution, that the irritation of the bladder was reflex depending on an unhealthy condition of the mucous membrane lining the uterus, which would probably be found to be rough and granular, this opinion was confirmed by the fact that the os and cervix uteri were found to be healthy, the sound proved the uterus to be elongated to the extent of about three-quarters of an inch. An exploration of the uterus verified this diagnosis. I shall by-and-by explain the mode of accomplishing this, and refer to the treatment you saw me adopt in the case, for the present it is sufficient to say that she will leave the hospital in a day or two, after the stay of but three weeks perfectly cured of an affection of ten years' standing.

But the mischief resulting from subinvolution of the uterus does not end here, for this abnormal state of the womb predisposes to the occurrence of that unhealthy condition known as granular ulceration of the os and cervix uteri, a condition which greatly augments the tendency to menorrhagia—thus the two causes which I have placed at the head of the list may be present in the same patient. The case of M. F. recently in No. 6 ward afforded a well marked instance of this. She has had twelve children and is now forty-eight years of age. She stated that ever since the date of the last confinement six years ago, menstruation had gradually become more profuse the flow continuing for a longer time than usual, the interval between the periods being correspondingly shortened. During the interval she suffered from profuse leucorrhœa and as a result was greatly debilitated.

On examining her extensive abrasion of the vaginal portion of the cervix uteri was found to exist, the os was patulous, the lips everted, and the mucous membrane lining the cervical canal could be seen in a thickened, highly vascular condition; the uterine sound penetrated to the depth of three and a half inches. This patient too was discharged after a residence of a few weeks in the hospital perfectly cured. She occasionally

appears among the out-patients but not from any return of the menorrhagia. I treated these cases alike by the application to the interior of the uterus in a manner I shall hereafter explain at length of the fuming nitric acid with most marked success.

In the foregoing case subinvolution was manifestly the primary cause of the menorrhagia the ulceration being altogether secondary; but often subinvolution exists alone, or on the other hand ulceration may exist alone, either condition being fully sufficient to give origin to severe menorrhagia. As an instance of the former the following serves as an example:—F. L., æt. twenty-four, married about a year, is a delicate young woman of lymphatic temperament; menstruation has always been profuse especially if she takes walking exercise or exerts herself during the flow. She became pregnant after the occurrence of the second menstrual period subsequent to her marriage, but having imprudently taken a long and fatiguing walk she aborted at the eighth week. The two subsequent menstrual periods were so profuse as to reduce her to a state of extreme debility. Ergot, gallic acid, and numerous other astringents were administered, but they failed to check the hæmorrhage. This was her condition when I saw her—On examining her I found the uterus to be considerably elongated, the sound passing to the depth of more than three inches; there was not any ulceration. The history of the case being altogether against the supposition of the existence of a polypus, I came to the conclusion that the menorrhagia depended on subinvolution, in fact that the uterus had never regained its normal size and tone since the miscarriage which had taken place two months previously. I therefore decided on carrying out a plan of treatment of the value of which you have had in the wards of this hospital repeated opportunities of judging—I mean the introduction up to the fundus of the uterus of ten grains of the solid nitrate of silver, which is left to dissolve there. This I accordingly did. It produced considerable pain which lasted for five or six hours but no further unpleasant results followed. I confined the patient to bed for three days and then allowed her to go about. Menstruation appeared at the regular time and was moderate in quantity. She became pregnant immediately after, and is now approaching the full term of utero-gestation. I wish to call your attention specially to this case, first as illustrating the occurrence of subinvolution as a result of abortion, a fact which though mentioned by Sir J. Simpson has been overlooked by many; next as showing the dangerous menorrhagia which may depend on this condition of the uterus; and thirdly, as proving the excellent results which follow the treatment I adopted. This point I wish specially to impress on you. You will find that ergot, gallic acid, and indeed all other medicines will frequently fail to check menorrhagia depending on subinvolution and that you must have recourse to treatment directed to the uterus itself. You must stimulate that organ to set up that healthy action by which it regains its normal size after pregnancy has terminated, a process to which as I have already told you the term "involution" is applied. With this view I unhesitatingly advocate the adoption of the treatment I practised in the preceding case I know of no other so efficacious. The mode of carrying it out is simple. You introduce the instrument which I now exhibit (Fig. 4) into the uterus just as you would an ordinary uterine sound. It is Sir James Simpson's "Uterine porte-caustique." It consists as you see of a hollow silver tube in size and shape closely resembling a sound; it contains a flexible stilette which fits it accurately. As soon as you are satisfied that its point has reached the fundus of the uterus you withdraw the stilette, and push up through the instrument by means of the stilette, a piece of solid nitrate of silver reduced to the requisite size and weight, till it is fairly lodged in the cavity of the uterus. In doing this there is but one caution requisite—namely, that as soon as the piece of nitrate of silver has reached the extremity of the porte caustique and before it is finally pushed out

of the instrument a point you can always be certain of by observing how much of the stilette remains still uninserted, you should withdraw the instrument to the extent of about half an inch, for if this precaution be not observed it is possible that the nitrate of silver might be forced into the substance of the uterine wall, instead of being left free in its cavity, an accident which though possible is very unlikely to occur. I have dwelt at some length on this plan of treatment because I am satisfied that its value is far from being fully appreciated. It is looked upon by many practitioners as heroic and dangerous. I believe it and I have practised it freely for several years to be simple and safe. I do not say that it is always sufficient and that a cure must always result but in my hands it has been productive of marked success, and in no single instance have I known it to produce serious symptoms. That pelvic cellulitis may under certain circumstances follow the introduction of the solid nitrate of silver into the uterus is quite possible, and I should not at any time be surprised at its occurrence; but the fear of this would never deter me from carrying out the treatment, for an attack of cellulitis is of much less importance than the continuance of profuse menorrhagia. But though I have on several occasions seen cellulitis follow on the use of astringent application apparently more mild, as yet it has not occurred in my practice after the introduction of the solid nitrate of silver. This treatment is no novelty. Dr. Evory Kennedy many years ago was in the habit of passing solid nitrate of silver into the cavity of the uterus, but he did not allow it to remain there. Subsequently Sir J. Simpson introduced the method I now advocate, and invented the porte-caustique.

In the case I have just related I was asked to see the patient just as the flow which had continued for nearly a fortnight ceased to appear, and as a full trial had been given to ordinary means without result and as the patient was in such a debilitated condition that a return of the hæmorrhage might be productive of very serious consequences, I seized the opportunity of its temporary cessation to carry out the treatment just detailed. Had I however seen her at an earlier period, I should at once have stopped the loss of blood by plugging the vagina. This is a mode of arresting the hæmorrhage which is always safe and as a temporary means perfectly efficacious. You have seen me practise it in our wards repeatedly. Of course in an emergency a sponge or a pocket handkerchief will do for the purpose; but when it can be obtained nothing answers so well as common cotton wadding. It should be cut in strips two inches wide the full length of the sheet leaving the paper to which the wadding adheres attached to it. These strips should then be introduced one by one through a speculum, a piece of tape or of twine being attached to the first introduced for the purpose of facilitating removal, the ends of the string being left outside the vulva. As many strips of the wadding as the vagina will contain are in this manner to be introduced, from four to six being the number usually required according as the capacity of the vagina

varies; the plug thus formed is withdrawn easily, for if the ends of the last strips inserted be laid hold of by a pair of dressing forceps and that they be rotated so as to coil the strips round them, each piece can be extracted without its breaking, while the first ones introduced are without trouble withdrawn by means of the strings attached to them. Any substance introduced into the vagina rapidly becomes very offensive, but this can be in a great degree remedied by smearing the strips of cotton freely with glycerine. The plug should in all cases be withdrawn after the lapse of twenty-four hours; to be re-introduced for a similar period if the hæmorrhage continue. Should you be unable to obtain wadding loose rolls of cotton or of tow will answer the purpose very well. You must however be careful to attach a string to each of the rolls first introduced and to keep the ends outside the vulva or you will experience much difficulty in removing the plug. This treatment is equally efficacious in restraining hæmorrhage depending on any of the causes I have enumerated as giving origin to menorrhagia, and should always be practised in severe cases.

As I do not wish to have to refer again to subinvolution I must diverge for a moment from the subject of menorrhagia to say that though profuse menstruation is nearly always the earliest and commonest symptom of subinvolution of the uterus, there may be exceptions to this rule as the following case proves. A young married woman was admitted into one of our hospitals during the past summer for what was supposed to be an ovarian tumour. She had been confined about three months previously of her third child. Hæmorrhage had followed delivery. She also appears to have been subsequently attacked by some form of pelvic inflammation. She recovered slowly and had not been able to nurse. The lochia ceased to appear during the attack alluded to and menstruation had not occurred since delivery. On passing the hand over the abdomen a large moveable tumour could be easily felt lying to the left side; it was very painful to the touch. After a few days this woman was discharged from hospital her case being considered unsuitable for any kind of surgical interference. As however she continued to suffer much distress she presented herself among the out-patients here, when a careful examination made with the aid of the uterine sound proved the tumour to be the uterus much enlarged and elongated, in fact it was a case of subinvolution with temporary suppression of menstruation. I admitted her into hospital, and introduced ten grains of nitrate of silver into the uterine cavity in the manner already described. This as usual caused some pain for a few hours, but it had the desired effect. It stimulated the uterus to set up the process of involution which the attack of inflammation had arrested, and in a couple of weeks she was discharged, the uterus having almost regained its normal size. When admitted the sound penetrated to the depth of five inches into the uterus.

Although the mode of treatment I have just detailed and which you have seen repeatedly carried out in this hospital, is the only one on which you can rely for the cure of menorrhagia depending on subinvolution, I am far from desiring you to suppose that I advocate its use in all cases, and have at once recourse to it whenever an instance of defective involution of the uterus occurs. On the contrary, I nearly always first try the effects of such medicines as are known to exert an influence over uterine hæmorrhage. Of these ergot and gallic acid (ten grains of each), administered every third hour are the most reliable, or if the patient be anæmic, I prefer giving ten drops of tincture of the perchloride of iron with twenty of the liquor ergotæ at similar intervals. The addition of ten drops of tincture of digitalis to the latter sometimes increases its efficacy, but I am reluctantly compelled to add that these and similar medicines very often fail to effect the least good.

## THE TREATMENT OF ECZEMA.

By J. L. MILTON, M.R.C.S.,

Surgeon to St. John's Hospital for Skin Diseases.

(Continued.)

5. COD-LIVER OIL is one of the most valuable remedies in eczema, and perhaps it would hardly be going too far to say that every chronic case is more or less benefited by it if taken long enough and in a proper way. Eczematous patients are generally very sensitive to cold, and means calculated to evoke heat seem usually to agree with them. The great obstacles to its use, the nauseous taste and the idea of swallowing a coarse animal oil, are soon overcome, and the result quickly compensates the patient for any disgust felt at the outset. Should the difficulty of taking it be insurmountable—as when it always brings on sickness, or when the patient is an infant at the breast—a broad fold of linen or flannel steeped daily in the oil, may be worn round the waist. The worst of this plan is, that it makes such a filthy mess that one can only employ it in the case of children and persons who are or can be confined to bed; but it certainly does good and patients get well and fat on oil used in this way.

I give the preference to Dr. De Jongh's oil over all I have tried. A pretty wide experience has satisfied me that the opinion I expressed some years ago as to its superiority, both in diseases of the skin and neuralgia, is well founded. I have heard men say that it cannot, and ought not to do any more good than the pale oil, because the colour and taste are simply due to the blood and bones of the fish being pounded up with the liver. But a fair trial of its powers will soon dispose of such puerile objections; and whatever the taste may be due to, most persons certainly find it less disagreeable and mawkish than the pale oil. Its cost, too, is less, as such a much smaller quantity is required. The dose should not be too large, never more than the stomach can bear comfortably. Grown persons seldom require more than five or six teaspoonfuls daily, often not so much; children bear relatively a much larger quantity and may take, even when quite young, two to four teaspoonfuls a day. It seems to sit best on the stomach after plain food, not always digesting so well after soups, stews, hashes, curries, &c. I think also it answers best when given directly after meals, but this is an affair of individual experience. The most agreeable vehicle for taking it in is a small quantity of wine like manzanilla, ginger, or orange, or coffee, the last suits some persons very well. Winter and spring are the most suitable times for taking it, and patients who cannot retain it on the stomach during hot weather, or lose their appetite for food under its influence, bear it perfectly well so long as the cold lasts. If the patient is to derive lasting benefit from its use it should be given for quite three to six months. Should circumstances require a trial of it to be made during the summer, I would suggest the use of the cod-liver oil chocolate made by M. Lebaigue, of 9 Langham street, Portland place. Each pound of it contains four ounces of oil. Should even this fail, I would recommend a trial of cream, from four to six ounces daily, or of the pancreatic emulsion prepared by Messrs. Savory and Moore.

6. But there are some stubborn cases which resist all these remedies, and in these a course of mercury will often give the *coup de grâce* to a disease which has defied everything else. The biniodide and bichloride of mercury seem to be the most powerful salts of this class. I at once admit that, after many trials, I have been unable to satisfy myself as to which is the most potent of the two; but, on the whole, I think the bichloride, and Mr. Startin seems to have had great success with it. The biniodide, however, is also an excellent preparation. About one-twelfth, steadily increased to one-sixth, of a grain of either will generally prove sufficient for a dose. This quantity may be taken once, twice,

or thrice a day, according to the severity of the complaint or age of the patient. I have repeatedly given young boys and girls a sixth of a grain daily with the best results. If given in a pill, the mercury should always be combined with the compound extract of sarsaparilla, or else with a sedative and aromatic, such as the extract of lettuce and the essential oil of peppermint or cassia, to prevent griping.\* When much pain of any kind complicates eczema, or when there is a tendency to diarrhoea, a quarter of a grain of pure opium may be added. If the form of a pill be objected to it may be given in some bitter tincture, such as cinchona or calumba; syrup of some kind or other should always be added when these salts are prescribed dissolved in water. The biniodide can always be given in solution by mixing bichloride of mercury and iodide of potassium in proper proportions, † But such adjuncts as tinctures and syrups cannot, I need scarcely say, be procured in hospital practice, and accordingly I have found that these preparations of mercury do not always answer so well with hospital patients, who almost without exception, complain of their depressing effect.

Almost the only complication likely to be met with in the treatment of eczema, that is, so far as one can be considered incident to the other, is rheumatism, the remedies for which are the same as in other cases: hydrochlorate of ammonia, iodide of potassium, colchicum and embrocations, of which by far the best I have seen is a combination of strong tincture of opium, containing quite four times as much opium as the ordinary tincture, or of the same strength as Cooke's black drop, chloroform, camphor liniment and soap liniment. ‡ Mr. Squire, who has himself suffered much pain from lumbago, recommends § seven

\* ℞ Hyd argyri perchlor., gr. j.;  
Extracti sarsae comp. liquid., ʒij. m.;  
Capiat. coch. min. ii. bis quotidie.  
℞ Hydrargyri perchlor., gr. i.;  
Extracti sarsae amp., ʒij. m.;  
Et divide in pil. xxiv. Capiat ii. nocte maneque.  
℞ Hydrargyri iodidi valv., gr. j.;  
Extracti lactuce, gr. xl viij.;  
— anthem., ʒi.;  
Olei cassiam ij. m.  
Et pil. xxiv. Sumat ij. nocte maneque.

† ℞ Hydrargyri perchlor., gr. j.;  
Syrupi rose ʒss.;  
Tinct. cinnam. e. ʒj. m.;  
Capiat. coch. min. i. bis quotidie es aque cyathe vin.  
℞ Potassii iodidi, gr. xxxij.;  
Hydrargyri perchloridi, gr. j.;  
Syrupi zingiberis, ʒss.;  
Aque cinnam., ʒiiss. m.;  
Capiat. coch. min. ii. ter quotidie.

‡ When the attack is severe and the pain very great I would advise the following:—

℞ Ammon. hydrochlor., ʒij.;  
Syrupi simpl., ʒss.;  
Aq. menth. divid ad ʒvj. m.;  
Capiat. coch. amp. duo tertiis horis.  
℞ Liquoris morphoe bi meccnatis, m xx.;  
Mist. camph., ʒi. m et haustus.

hera dead. sumandus.

Thirty minims of chlorodyne may be substituted for this draught or hydrate of chloral may be given. The latter did not answer at all in my practice. In doses of less than a scruple it seemed to have no effect, and in larger ones it brought on, especially after the first night or two, great cerebral excitement. At the same time the part affected should be dry-capped with any materials at hand, for quite an hour, and the following embrocation applied by means of a flannel steeped in it:—

℞ Guttae nigrae (Cooke), ʒij.;  
Chloroformi, ʒi.;  
Lin. camph. comp., ʒi.;  
— saponis, ʒvj. m et embrocatio.

Over the flannel should be laid a pile of soft cotton wool, medicated cotton wool as it is commonly called—kept on by a baudage. After the pain has yielded the patient may take

℞ Potassii iodidi, ʒij.;  
Aque ʒij. m.;

Coch. min. ii. bis quotidie sumend.

The simplest way of taking this is to put the dose into the first portion of the fluid drunk at any meal.

℞ Extracti colch. acetici;  
Pulve hydrargyri an, gr. vj.;  
Extracti hyoscyami, gr. xij. m.;

Et pil xii. Sumat i. omni nocte.

parts of belladonna liniment and one of chloroform sprinkled on spongio piline to be held on the part. It is a very useful application, but I doubt whether it is suited to an eczematous skin. In all the trials I made of it, in persons of this tendency, eczema came out in the vicinity of the places it was applied to.

The pressure of inflamed lymphatic glands, induced by eczema, and of the troublesome thickening of the skin, sometimes even extending to the subcutaneous cellular tissue, and ending in the formation of abscesses, are complications over which we have little control. Scalding with very hot water, followed by the use of ice or evaporating lotions, and subsequently with tincture of iodine or a solution of nitrate of silver, ten grains to an ounce, are nearly all the remedies which I know of likely to be of much use. In unhealthy children, swelling of the glands at the back of the neck, from eczema of the posterior part of the scalp, is extremely apt to end in abscess unless much stronger measures are employed than we can generally adopt.

*Change of Air.*—Supposing all this has been done, and that the eczema, though better, is not quite well, or, after being over and over again cured—so far at least as external symptoms are concerned—it perpetually shows a tendency to return, what is to be done? Shall we send the patient for change of air to some mineral spring, or give tar, cantharides, or some other drug recommended as a last resource?

To judge from my own experience I should say most decidedly not. *I never yet saw such agencies under such circumstances effect a cure;* and I believe the best plan is to leave the case to nature, feed the patient as well as possible and give no medicine whatever for a period of several months; at the end of which time it will often be found that the health has somewhat improved, remedies long previously given perhaps aiding a little in the work, and then any slight means will frequently remove all traces of the disease. Almost the worst case I ever saw was put right in this way. The patient had been in a most deplorable state from eczema and exhaustion for years, and at the end of a long course of treatment was still worried by the perpetual recurrence of the complaint. I recommended him to take no medicine whatever, to have meat twice a day, and fat ham or bacon once daily, at least four or five glasses of port wine and one or two of old Scotch whisky every day, to eat brown bread in place of white, and to take work as quietly as he could. These instructions he faithfully carried out. In the course of two years he had increased above a stone in weight, and for several months he had only suffered occasionally from a stray patch of eczema, which invariably disappeared under the use of dilute nitrate of mercury ointment. One year later his condition had improved still further, and at the present time he reports himself quite well.

(To be continued.)

## ON THE CAUSES AND CURE OF PROSTATIC STRICTURE.

By R. UNICKE RONAYNE, F.R.C.S.I., L.R.C.P.E., &c.  
Youghal Infirmary.

THERE are few, if any, affections within the cordon of surgery more anomalous in character or eccentric in conduct than hypertrophy of the prostate; it is a simple enlargement of the tissues of the gland, devoid of all structural change, without diseased growth on the one hand, or degeneration on the other; with no deviation from health beyond its increased size, and yet by that means alone producing such changes in its relations to other parts as bring it within the pale of disease in most formidable phases. It is a morbid anachronism, passing quietly over the periods when other glandular systems are generally stirred by active or passive enlargements, and lying in wait for advanced life, ready to spring into

action at a time when these are fast tending to inaction or atrophy. It is not health, for soundness of all functions cannot co-exist with it; it is not disease for in itself it is the most innocent of growths; it is as innately harmless as the fat cells in the omentum of the typical Aldermen, yet as dangerous as the same prove when hiding in the fibres of the heart; in fine, although benign in itself, it is so unfortunately situated in relation to other and important parts, that it generates disease on disease, and, proving remarkably intractable to treatment, leads its unhappy victim in a long series of ills through a shortened life of misery to a deplorable and often disgusting death. I shall, however, for the sake of clearness, speak of it as a morbid state. Of the causes which give rise to this hypertrophy, little is satisfactorily ascertained, and, strange to say, conjecture has been notably silent; indeed, few writers have indulged in speculations on the subject. It may have been considered a profitless venture, yet many seemingly as fruitless have absorbed much valuable time and brain work; it is because, however, I conceive that some little advantage in prevention or treatment may result, that I devote a few lines to their consideration. In this search analogy is of little help, as the prostate seems ostracised from association with all other glands, even the thyroid to which some consider it allied, differs materially from it in health; I think we may fairly set down as tending to lead to prostatic hypertrophy all acute and sub-acute inflammations of the parts, whether these arise from injury, the metastasis of blenorrhœa or struma, as resolution from such attacks is pretty certain to leave behind a thickening or condensation of tissue, if not an active hyperæmic state, which in time assumes a more definite form, and eventually lapses into disease. Calculous disorders, although often resulting mechanically from chronic prostatic enlargement, may sometimes provide the initiative irritation. Constitutional influence often plays an important part in the induction of this condition, the gouty, rheumatic, and scrofulous diathesis leading frequently to its presence, by keeping up a continuous irritation, which results in congestion and ultimate hypertrophy. The excessive and prolonged use of stimulants tend, by a similar action, to a like result; but, I believe the key to the most frequent source of chronic prostatic enlargement will be found in derangement of the generative functions, arising from continuous and undue sexual excitement.

The uses of the prostate seem entirely and intimately bound up with the workings of the generative system. The gland is little better than rudimentary previous to puberty, when it first assumes the importance of a supplementary organ; from that time it sympathises actively with the varying fortunes of the sexual organs until the second change of life, the decay of manhood, when we find it again rising into unwonted activity; its two greatest alterations being thus associated with the birth and death of virile power. Again, all venereal excesses induce irritation and tenderness of the gland, quickly followed by slight enlargement; in youth, where remedial measures are stringently adopted, this is generally transitory, but persistence in the cause often renders the affection permanent, whilst in old age it more easily adopts a chronic type, as the constitutional sources of derangement are then more numerous. The exquisite tenderness of the prostatic urethra under catheterism, and the marked enlargement of the gland present in aggravated forms of spermatorrhœa, aptly illustrates the disordered state to which the parts may be reduced by contained undue excitement. Then we know that chronic prostatitis goes hand in hand with sterility. That the disease is common in those whose desires have long outlived their capacity for compassing them, and, that on the other side, men who have retained their potency to advanced age seldom suffer from it: Combining these circumstances, I am induced to adopt the belief, that the initial irritation which often eventuates in senile hypertrophy, may be surely produced by the

frequent long sustained indulgence of inordinate sexual passions, whether these be gratified naturally, or by the more debasing and injurious habit of masturbation.

That its rapid growth about the fall of life is due to a bold attempt on the part of nature, to repair damage and sustain the waning local strength; that most glands attain it in greater or less degree, but, that it becomes noticeable only when constitutional diathesis or inordinate vice have superadded special irritation and thus given a morbid impetus to a healthy action. On the symptoms of prostatic enlargement, it is not necessary here to dwell, we all know that as the gland increases in size, a gradual change is effected in the local urethra which is twisted or flattened, or even somewhat dilated, and elongated, as the growth is limited to one, or both, or the false lobe, or extended to the entire structure; that these changes soon effect a diminution in the volume and force of the urinal stream, besides causing increased frequency of micturition, as well as a sense of weight in the perinæum, sometimes dull aching pains in the loins, and occasionally tenesmus to such a degree that supposed piles are as often complained of as the true ailment. As the growth increases the symptoms become more aggravated, the rising lip of the gland prevents the complete evacuation of the bladder, the urine stagnating becomes ammoniacal and throws down phosphates; the bladder irritated by this state of things, and exerting increased muscular force to overcome obstruction and meet the pressure of retained water, becomes thickened in its coats, increased in size, and soon takes on a state of chronic inflammation, this, with some further trivial exciting cause, reacting on the prostate, causes the hypertrophied gland to become additionally congested, the increased swelling closes the already too contracted portal of the bladder, and a typical case of retention from prostatic stricture is established. The treatment of prostatic hypertrophy and stricture dependant upon its has made little, if any progress, since the time of Sir Everard Home. Then, and at various times since, attempts at its reduction or removal by medicinal means have been repeatedly made, with, however, but poor results.

Many agents have found advocates and for a time favour, but on the whole, modern experience has amply shown that none of them are worthy of much reliance. Conium was at one time empirically given in large doses with no benefit beyond a temporary and dangerously delusive relief from pain; during the mercury mania that drug was extensively administered, with no effect on the tumour, but it is to be feared, a very decided one on the constitutions of the unfortunate patients. Chloride of ammonium has also been fairly placed on trial and a verdict recorded against it; iodine long retained great and still holds some repute; it first came into this use through the absorbent power it occasionally swayed over bronchocele which was considered in some inexplicable manner allied to senile hypertrophy, from its action on enlarged glands in general, and its supposed speciality of promoting absorption of the mamma and testis. At the present time, the only agent that seems at all to hold ground is the iodide of potassium, first used for the purpose by Mr. Stafford, some thirty years since; he not only administered it by mouth, but also in suppository, and by means of ointment applied directly on bougies. If his reports are to be credited, and we see no reason why they should not receive some respect, it proved undoubtedly useful in his hands, and when we find a man of such keen observation and unflinching truth as Sir Benjamin Brodie, believing in its power in reducing subacute if not absolutely chronic enlargements, we may fairly set it down as at least possessing some efficiency. For my own part, believing as I do, that in eight cases out of ten the disease is the ultimate result of chronic sexual irritation, whether natural or onanistic, I would suggest that a well directed attempt to prevent it might be made with the hope of benefit, and that the truest method of combatting it, is to forestall the enlargement by resolutely setting ourselves

to remove all irritation as early as it comes under our notice by the use of such remedies as our experience supplies, but above all, by insisting on such a complete change of thought and habit, as will remove the patient from the ever recurring stimulus. In such cases I find the bromide of potassium unquestionably useful in lowering the sexual orgasm, and in helping to lessen local congestion. The introduction of the silver catheter is almost always needed, and when anointed with extract of belladonna, is especially serviceable in blunting the sensibility of the part. For the rest, tonics, wholesome unstimulating diet, sea-bathing, and healthy exercise of mind and body generally suffice. It however frequently happens, that the possessor of an enlarged prostate, letting the premonitory symptoms pass with little notice, or attributing them to hæmorrhoids, is not aware of the unpleasant transformation taking place in his internal economy until it suddenly declares itself by retention of urine, the climax being capped by exposure to cold, horse exercise, comparative sexual excess, or a drinking bout producing a determination of blood to the part and consequent closure of the vesical gate. In such a case, time generally permits of no procedure other than the immediate relief of the distended and painful viscus by catheterism, and this end is not always attained without considerable difficulty, especially as the parts are often very irritable, and membranous spasm has sometimes to be overcome before the instrument meets the organic lesion; patience and gentleness of manipulation, and above all practice are here essentially necessary to avoid doing irretrievable injury and will almost always lead to success. In about thirty such cases, I have never been obliged to resort to forcible entry or paracentesis vesicæ, I am accustomed, however, to use an instrument bent to a much sharper curve than that generally advised in such cases; I find by repeated trials that a full sized elastic catheter, or the stilet, the lower half of which is bent into half a circle, with a further slight in-sweep of the point passes easily where all differently shaped instruments fail. The incurve at the point is of great importance, as it enables the tube to ride clear of the promontory of "Home's lobe," when that abnormal structure is the impediment and enter the bladder without forcing the surgeon to the disgusting resource of passing the finger into the rectum or to the admirable but sometimes hazardous "Hey's manœuvre." I know of but one serious objection to the use of an instrument thus curved, namely, the difficulty, if not impossibility, of using it, where great rotundity of abdomen exists. I have no doubt that some extreme cases may be met where this would be an insurmountable objection, but, in my own experience, I have succeeded in passing it on fairly obese people by placing them in bed, with the hips raised by a pillow, and the shoulders lowered, and then adopting the "*tour de maître*." There are two points connected with catheterism, which, though not strictly pertaining to my subject, I cannot pass by in silence, the first concerns the use of the gum catheters without the stilet, as advised by some excellent authorities. I can see no appreciable advantage from this; I do not believe that it is less likely to produce spasm than the armed instrument, and I know that it is much more difficult to pass, as it is led away by every tempting sinus, bends on the least pressure, often twists out of control and oftener hitches against the prostate than not. As to passing the unarmed instrument down to the obstruction, and then arming it for the purpose of using "Hey's manœuvre," I think it a most dangerous practice, offering every facility for the production of false passage, urinary infiltration, or other complications. I have when a student seen not a little evil result from such a course, and I should be reduced to great straits indeed before a lopting it. The second regards the propriety of permitting the patient to use an instrument himself, this I am decidedly opposed to, unless the patient be so situated (in the country for instance), that medical assistance becomes uncertain or unattainable, as I have seen much irritation

produced by the constant practising to which such persons are prone to give away, and if complete retention sets in, pain and anxiety takes away their heads, and so unmans them that they are pretty certain to injure themselves in their nervous fumbling haste. The temporary relief of this first attack being effected, means must be taken by local, antiphlogistic, sedative, and general alterative treatment, to reduce whatever inflammation exists and restore the interrupted balance of power. Free leeching to the perinæum may be had recourse to, the bowels relieved by cooling enemata, the acrimonious nature of the urine lessened by demulcent drinks, and corrected by acids or alkalies, whichever are called for, and sedatives should be administered by mouth and rectum, congestion of the abdominal viscera must be lessened, whilst the strength is maintained by nourishing, but unstimulating food, under a course of such remedies the urgent symptoms subside, and the health previously enjoyed seems again to be attained, but this is scarcely the case, for a hyperæmic condition of parts still remains, slowly gathering strength, and hanging like a Damocletian sword over the safety of the patient, always threatening and ready to fall and crush or maim at the turn of a hair. Care may do much to ward off any sudden attack, but no care can avert the tendency to steady growth which the disease manifests when it has once deeply rooted, and which, if life be sufficiently prolonged, is pretty sure to culminate sooner or later in a renewed attack of retention, this time the result of non-inflammatory hypertrophied tissue. Then arises a state ever burdened with pain, disquiet and wearying anxiety for the sufferer, and full of harassing profitless work for the attendant. Chronic prostatic retention with all its sickening adjuncts has set in, the bladder requires to be emptied two or three times a day, sometimes oftener, and if the patient's residence be at any distance, the frequent and often ill-timed calls become almost unendurable, and all this worry and trouble produces at best but a passing relief. I have often been recalled to cases within two hours of my visit to find the bladder again distended, the kidneys relieved from pressure having acted in the mean time with redoubled energy.

In such cases I have long adopted a course which, although it does not receive the approval of many of the fathers of surgery, has in my experience proved more beneficial than all other usual measures put together. I allude to the treatment by retained catheter.

When I commenced practice I was strongly opposed to this mode, having been prejudiced against it both by teaching and reading, but at that time I never supposed that by it could be realised the satisfactory results which I have since obtained. My procedure is simple, I introduce an instrument of the shape above described, and retain it by woollen ligature, steeped for cleanliness in a solution of carbolic acid, stopping the mouth with a peg removable at the patient's will, this gives him very fair control over the bladder, and usually produces as much mental quiet as it does bodily ease, he being assured of his own safety by holding the necessary means of relief in his own possession. Sometimes the instrument is well borne from the first, and the case rapidly progresses towards cure, but often it gives rise in a few hours to much pain and disturbance: in such a case there is nothing for it but to remove the catheter, and fall back on the usual system, taking care however, to adopt such means as may serve to lessen the irritability of constitutional tone, and watching closely for a favourable time to resume the trial. If the uneasiness however be not severe, or becoming gradually more aggravated, it is well to sustain the treatment, and adopt collateral means to correct the intolerance which then generally dies out in a few days, and thenceforward the intruder is permitted to remain in peaceable possession. In fact, the parts become accustomed to its presence, and in truth, it gives much less annoyance by its permanent occupation than it would by frequent fresh introductions over the sensitive and resisting passage. The catheter is then removed every two or three days and

then examined, lest it be cracked or eroded, and when cleansed re-introduced, or, if it be in the least damaged, a new one substituted.

This treatment is continued for a period varying according to the peculiarities of every case. When, on removing the instrument some day, the patient tells you that he feels he is again capable of making water, and has regained the natural control over the bladder. I do not, however, permit the permanent removal of the instrument until I am satisfied that the local health is as fully restored as it is ever likely to be, and even when it is determined that its use may be discontinued, this is done gradually, being first left out by day, and worn by night, as at the latter time the continued pressure on the trigone is more likely to give rise to a desire for evacuation of the vesical contents, until by degrees it is altogether discarded.

Since I have adopted this plan, I have treated many well-marked chronic cases, occurring in old men, whose ages run from sixty to seventy-three, to a successful issue. These under the ordinary treatment would certainly have degenerated into hopelessly incurable disease with pus secreting bladder, disorganised kidneys, and a person emaciated and loathsome to a degree, sodden from the dribbling of ammoniacal urine, and honey-combed with festering bed sores. Thus, then, in my humble judgment the treatment by retained catheter offers several advantages to counterbalance its slight risk, over the constant and unsatisfactory necessitous use of the instrument for temporary, and ultimately unprofitable relief, not the least of which is the chance of ultimate cure which it holds out. After the first day or two its presence is practically less irritating than the repeated disturbances arising from recurring instrumental inroads into unwilling parts, which keeps alive an abortive resistance to each fresh advance, thus engendering a constant and exhausting excitement which reacts disastrously on the bladder and kidneys. Whilst under the treatment I recommend the parts soon become reconciled to the presence of the friendly invader, and accustom themselves to tolerate its society in consideration of the peace and security it confers. On the bladder this method exercises a most benign influence, that unfortunate viscus which has long remained like a stagnant pool unemptied, a foul receptacle for decomposing urine, filthy, mucous, and unhealthy urinary deposits, is quickly washed out by the pure and free secretion of the unlocked kidneys, its ungainly distension gradually subsides, its mucous membrane improves in character, and it recovers much of the power and sensibility of health. The kidneys freed from the restraint of distended ureters, are enabled to carry on their important eliminative processes to the great benefit of the system at large, and the mind relieved from a depressing load of anxiety, torturing suspense and watchfulness, materially helps by its bright cheerfulness to bring about a more healthy physical state than had for a long time previously been enjoyed.

Its action in producing these good effects is not easily explained; besides relieving the distension and consequent congestion of the bladder and cleansing and resting that organ and those dependant on it, it must exercise some directly absorptive power over the prostate itself, else how could the retention dependant on chronic hypertrophy ultimately disappear under this method and no other? On this matter I am happily reduced to conjecture as no death whilst under or after treatment has given me an opportunity of verifying my opinion by cadaveric examination, and in such a belief I see nothing improbable. That a partial absorption of the gland might be obtained by mechanical means, has been hoped for by writers of ability and eminence even to the present time, when Sir H. Thompson, the ablest authority we know on such subjects, has employed dilatation by water in expanding india-rubber tubes, with he admits but little success, and I see no reason why absence of irritation and gentle long sustained pressure, should not alter the offending portion of the prostate and neck of the bladder sufficiently

to admit of at least an approach to cure. At all events, setting such speculations down for what they are worth, we still have the unbending fact that the cases I write of have been cured by this means, and I can safely say, that I never saw one cured by the ordinary treatment.

It may seem surprising that such a local effect could be produced without the action thus set moving running on to ulceration and producing a much worse state of things than it was intended to rectify. I have little doubt that such would be the result of ill-timed persistence in the retention treatment in ill-chosen cases, but when we remember the blunted sensibility which the constant companionships with irritating urinary deposits has effected in the parts, we can easily understand that the change to a clean instrument is a relief rather than an infliction, and besides we see how tolerant the bladder often is of some calculi, and we know that foreign bodies such as portions of catheter, cloth, or even bullets are borne for a long time with comparative impunity. The entire success of the measure depends on selecting cases where the affection is chronic, and the attendant symptoms at least not inflammatory, and in taking care that it is never pushed to indiscretion by depending too much on chance, and too little on judgment. Daily watchfulness and care are absolutely necessary, but no greater attention is demanded than the profitless catheterism of the ordinary treatment would enforce.

Another point of material importance, and one which cannot be disregarded, is to ascertain that the kidneys are free from disease before attempting this treatment, neglect in doing so is perfectly unwarrantable, and most assuredly sooner or later entail disaster, as cases of nephritic disease are acutely intolerant of almost any interference. For the rest a carefully regulated unstimulating and nutritious diet, the occasional washing out of the bladder with tepid water, to which a little chlorate of potash or tincture of opium, may be advantageously added if much mucus or deposit be present, the free use of opium, chloral, *cannabis Indica*, conium, or other sedative, the administration of the iodide of ammonium or bromide or iodide of potassium, to stimulate absorption and lessen sexual irritation, together with change of air and ease of mind, combine to favour a restoration to local and general health.

In conclusion, I would recommend a trial of this mode of treatment to those union hospital and dispensary medical men, who have hitherto found a case of prostatic retention the very *bête noir* of existence.

## CLINICAL REPORT OF CASES OF SMALL-POX

ATTENDED DURING THE  
PRESENT VERY PREVALENT EPIDEMIC.

By J. H. WATSON, M.R.C.S.

By kindly inserting a few remarks under the above heading in your valuable journal, you will oblige me as well as the public, as my own list of sixty-one cases of the disease manifest so strongly the utility of vaccination. If every practitioner would just take the same little trouble in their respective localities, the bugbear raised by anti-vaccination humbugs to frighten women and children would very soon vanish out of sight.

In a practice extending over thirty years, I may here observe I have never met with ill of anything resulting from my own vaccinations, and a summary of the cases above alluded to of variola show the immense protective power of vaccination generally. I find then amongst patients attacked, who had been vaccinated in infancy principally, a percentage of deaths between seven and eight only, and of severe cases (a few of them confluent) between nine and ten only, whereas amongst the *unvaccinated* the deaths averaged forty per cent. or two-

fifths, and the severe cases sixty per cent. or three-fifths. The ages of the sufferers are very low, nearly all being infants and adolescents. In one case only the age reached forty-eight years. As to sex, I find six of one and half a dozen of the other, in fact all but equal.

The period I have taken my cases from is from 8th November, to 20th May, being nearly *six months*, during which time the epidemic has predominated in this locality, Hoxton. But one of the above cases were re-vaccinated.

It is therefore a pity that vaccination should not be thoroughly carried out, so as to leave no person unprotected.

## Hospital Reports.

KING'S COLLEGE HOSPITAL.

SATURDAY, JUNE 10.

*Removal of recurrent fibroid growths—Oblique flap operation of the thigh for removal of recurrent fibroid tumour.*

(Under the care of PROFESSOR WOOD, F.R.S.)

THE first case was a man who had a series of recurrent fibroid growths under the skin of the thigh. Professor Wood dissected them all very carefully out from between the skin and fascia lata, and in doing so the Professor took care so to arrange his incisions that union might take place as rapidly as possible. After their removal a strong solution of chloride of lime was applied to the wound, and it was then dressed.

Professor Wood observed in reference to this case that the history the man had given was as follows:—Some months ago he had had a large boil or carbuncle on the outside of the thigh which had sloughed, and that subsequently these hard tumours had made their appearance. The Professor thought however that it was most probable that the so-called carbuncle was in reality a fibroid growth which had sloughed. There was another fibroid growth near the perinæum which it was intended to remove hereafter. It subsequently sloughed, however, and the patient left the hospital pretty well.

The next case—for the notes of which we are indebted to Mr. La Motté, Professor Wood's dresser—is as follows:

The man was admitted on the 2nd June. He stated that twelve years ago a small growth appeared from the side of the left knee and grew in a twelvemonth as big as a pear. It was then cut off by a surgeon and the wound healed rapidly. Seven years afterwards the growth re-appeared, and about four years ago it was removed and the wound again healed. Two years after this operation the tumour re-appeared for the third time, occupying a much larger space than before, has been steadily increasing in size, and at times is very painful. An attempt was then made by a surgeon to burn it off with chloride of lime paste, which however only destroyed a portion of the surface but in no way relieved the pain. The tumour now occupies the whole anterior surface of the knee, is circular in shape, and about three and a-half inches in diameter.

The man is healthy looking and young for his age.

Professor Wood stated to the class that the tumour was of the recurrent fibroid type, and that it had probably commenced to grow on the patella; it was moveable, and apparently not connected with the joint. He was ordered to take iodide of potass and tartrate of iron three times a day.

On the 10th of June he was brought into the Theatre to be operated upon, Professor Wood having determined beforehand to try and dissect the tumour off the knee if it were not connected with the joint. But on the other hand if it were he should proceed to amputate. The at-

tempt to dissect out the tumour having failed in consequence of its extensive adhesion to the capsule of the knee-joint, Professor Wood then amputated at the lower third of the thigh. The flaps were made in a way peculiar to the Professor—they were *antero-oblique*. The stump was then dressed, and the patient sent to the ward.

Professor Wood remarked to the class that this case was rather an unusual one, necessitating the substitution of amputation instead of mere excision of the tumour for the reasons already given.

The operation the class had just witnessed was the one he had introduced to the Profession, and which he considered most advisable for amputation of the thigh—"the oblique."

Now, what is really wanted in amputation is as follows:—A good covering of skin for the bone—muscle is not required as it becomes absorbed. Your anterior flap should be the longer of the two, and so establish a good drainage and prevent bagging of matter, *desiderata* not always obtained by the antero-posterior operation; and, finally, you have as good a covering for the limb by the oblique as by the antero-posterior. In all amputations you should take care to trim tendons as they slough and give much trouble; cut nerves also if they are likely to be subjected to pressure in the stump, and always keep, if possible, the arteries long, so that the stump may be well supplied with blood. Lastly, do not employ your bone nippers too freely or small ends of bones become absorbed.

On examining the stump the following day it was found healthy, and proceeding satisfactorily, but the patient himself seemed to have felt the shock of the operation a good deal. His face is pale and has an anxious expression of countenance; has had cramps and twitchings in the stump, and slept badly last night; the pulse 132 in the morning and evening, and the temperature was 102 in the morning and 104 in the evening. He gradually got worse, apparently suffering from symptoms of exhaustion, notwithstanding every treatment, medicinal, hygienic and dietetic were adopted. The temperature on the 14th rose to 104; on the 16th the pulse rose to 132, and the temperature 104. He then became restless and delirious, and the skin quite dry. On the morning of the 17th he sweated profusely, and died at 10 a.m.

*Autopsy.*—All the internal organs were more or less friable—no marked disease in any of them; walls of the ventricles and some fat about the heart. Heart and all the blood vessels had the appearance of having been stained a dark red colour, conveying the idea that the red corpuscles had melted, and the hæmatin had been deposited. Femoral vein was plugged in two places, one above the other below Poupart's ligament; the part of the vein above Poupart's ligament was tinged with red; the part below was healthy. There were no plugs in the heart or valves. The blood was fluid. A small quantity of pus was found in the bursa under the left deltoid muscle, and the aorta was stained to some extent by imbibition of the blood-colouring matter. Professor Wood considered the termination of the case as very remarkable, inasmuch as there was scarcely a single symptom during life to lead one to suspect the presence of such important pathological conditions of the pyæmic state as they had just witnessed; and pointed out the insidious character of pyæmia.

## METROPOLITAN FREE HOSPITAL.

(Under the care of Mr. SHEFFIELD.)

IN a recent visit to this hospital we remarked a case of resection of the first joint of the thumb in a man, aged forty, who had cut into the joint whilst boning a fowl, his trade being a poulterer. The joint became disorganised, and the question of amputation was spoken of, but Mr. Sheffield wished to try to save the thumb. About a week ago, the ends of the two phalanges were removed, and the

man has made a good recovery. This operation seems rarely to have been performed. There was also two cases of epithelial cancer in the wards, under Mr. Sheffield's care, both of which had been operated on. The operation on the penis performed a week before our visit, and the wound was healing kindly. The man with epithelioma of the lip had been operated on the day previous to our visit. The man had been a great smoker, as is usual, we believe, in such cases of epithelioma of the lip. Mr. Sheffield thought that the case might be permanent in the case of epithelioma of the lip, but that the disease would probably return in the case of the epithelioma of the penis operated on. We also saw a little boy, aged five, on whom Mr. Sheffield had operated the day before for stone in the bladder by the median operation. The stone was the size of a cran. The child was doing very well indeed. Dr. C. Drysdale has two cases of disease of the liver in the wards, one of which is a case of enlargement of the organ in a man suffering from rupial syphilitic sores in the back and abdomen, where the liver descends on the right side two inches below the level of the ribs; and the other is a case of carcinoma of the liver in an aged man, with extreme jaundice and enlargement of the liver as far down as the umbilicus. There is some talk of the hospital being soon enlarged, but nothing definite is arranged on this point, although it is assumed that funds for the purpose might with ease be raised.

## The Composition of Secret Medicines.

DR. WITTSTEIN'S *Handbook of Secret Medicines*, recently published, contains much interesting information on the subject. The articles are arranged in alphabetical order, and a short history is attached, giving the originator or manufacturer, the diseases which it pretends to cure, a description of the physical properties and style in which it is put up, the retail price, the pretended constituents, the true composition, and the actual retail value if made in a respectable apothecary's shop. We extract the formulas for a few articles only, which may be of some interest to our readers:

*Granular Effervescent Citrate of Magnesia*, by Bishop, of London, consists merely of bicarbonate of soda and tartaric acid.

*Pommade des Châtelaines*, a hair invigorator, consists of benzonated lard and some volatile oils.

*Magnesian Aperient*, by Moxon, of England, is, according to Siller, anhydrous sulphate of magnesia thirty-one, carbonate of magnesia fourteen, bicarbonate of soda thirty, tartaric acid twenty-five parts.

*Hoff's Extract of Malt* has been repeatedly altered in its composition. It is now a good beer, of a pretty constant alcoholic strength of 3 per cent., but varying in the amount of extract between 5.3 and 10 per cent. The beer sometimes contains an infusion of a bitter herb (buckbean, blessed thistle) and of the bark of *Rhamnus frangula*. According to its original recipe, beer was mixed with a small quantity of strong infusion of marsh mallow root, coriander, staranise, and grains of paradise, and with some simple syrup, glycerine, oil of lemon, or of orange and beer colouring (caramel). The consumers can make it for, at most, one-sixth of its price.

*Zimmermann's Extract of Malt*, which, like the former, comes likewise from Berlin, is similar in composition.

*Matico Injection*, by Grimault, of Paris, for gonorrhœa, is made, according to Bjoerklund, by dissolving four grains sulphate of copper in 8 oz. infusion of matico (from  $\frac{1}{2}$  oz.)

*Syrup of Horseradish*, by Grimault. Hager gives the following: 50 p. each of fresh scurvy, grass, buckbean and watercress, 60 of horseradish, 40 of fresh orange berries, are infused with 3 cinnamon in 50 p. white wine, and after a day expressed; 250 p. sugar are dissolved in the filtrate.

*Iodinated Syrup of Horseradish*, by Grimault, contains 10 iodine and 5 potassium iodide in 8,000 of the former.

*New York Pills*, by Sampson, of New York. The  $\frac{1}{2}$  grain pills consist of powdered cocoa 25, extract of cocoa 30, powdered iron 35 parts.

*Brandreth's Pills* contain resin of podophyllum, inspissated juice of poke berries, saffron, cloves, oil of peppermint.

*Holloway's Pills* are composed of aloë, myrrh and saffron.  
*Coca Pills*. According to Hager and Jacobsen, composed

of powdered coca, and extract of cocoa in about equal quantities; value about one-fourth of price.

*Morrison's Pills*, 2½ grains each, consist of aloë, cream of tartar and colocynth; another kind contains the same ingredients, besides gamboge.

*Radway's Ready Relief*, according to Peckolt, is an ethereal tincture of capsicum, with alcohol and camphor.

*Radway's Renovating Resolvent*, a vinous tincture of ginger and cardamom sweetened with sugar.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 19, 1871.

### GENERAL MEDICAL COUNCIL.

LAST week we were able to present our readers with a report of the proceedings of the Council up to the previous Saturday, and to add in our leading columns a few notes on the more important points discussed. The Session closed on the following Monday, which was chiefly occupied with a free discussion of the Report of the Committee on Education. This underwent a few alterations, and Dr. Risdon Bennett made some uncalled-for remarks on ourselves and contemporaries in giving publicity to that Report prior to its receiving its final touches. It would be strange were such publicity to be denied, and we regret much to observe in one or two Councillors a hazy notion that they should keep their affairs as quiet as possible. This is only a reflection of the plan that has yielded such disastrous results in the Corporations, which discuss most important questions in secret. We hope this is the last exhibition of such a disposition. Publicity is the one thing that has redeemed the Council from the vices that have done so much evil in the Medical Corporations.

#### THE CONJOINT SCHEME.

The question of Conjoint Examining Boards was brought forward by Dr. Parkes, who remarked on the little effect that the recommendation of the Council seemed likely to have, and moved that unless a scheme should be completed by the end of this year for each of the three kingdoms, that the President should seek an interview with the Privy Council with a view of urging that such schemes should be comprised in the expected legislation of 1872. He had

heard that in Scotland there would be no difficulty, but in Ireland he feared a Conjoint Board could not be formed. The plan of the two London Royal Colleges he commended, but it had the great defect of not comprising the Society of Apothecaries, which would therefore be free to grant its license, and, of course, its licentiates would be entitled to register. There was a good deal of objection to any threat being held out to the Licensing Bodies, and ultimately it was resolved that the Council should meet early next year to receive reports as to what might be done in the meantime, and take such steps as might then seem needful.

#### CLINICAL INSTRUCTION.

Having thus completed a statement of what the Session of the Council comprised—we turn back to one or two points respecting education which, as we predicted, was the chief business.

An attempt was made to lay down the manner in which clinical instruction should be imparted, and it was even roundly stated that little or no progress had been made in this generation. We are glad the attempt failed because we believe great progress has been made, and we do not think teachers should be fettered by too many restrictions. It is ridiculous to prescribe the mode of clinical instruction, when every teacher who loves the work will do best by following his own bent. Some very curious statements were made in the Council which might have been made very truly perhaps when the Councillors were themselves students. From experience in the hospitals of London we know that many improvements have been effected, and others are in progress. Only last winter we drew the attention of our readers to the arrangements so successfully in operation at the London Hospital. We attended regularly a large proportion of the clinical teaching expressly to note it, and we ask any Councillor who doubts whether we did more than justice to it to follow our example. A few clinical lessons from Dr. Herbert Davies or Dr. Andrew Clark, who take essentially different methods, and are equally successful, will convince anyone that we are by no means destitute of teachers who can and will train pupils most efficiently. We did not witness personally the teaching of the other physicians, or the surgeons, at the London Hospital, but we have obtained evidence of its excellence, and we draw attention to this hospital because the arrangements have been carefully carried out by the teachers without any suggestion from without—much more without compulsion.

#### PATHOLOGY.

It was proposed to enforce systematic lectures on this subject, but at last agreed, simply on the proposal of Dr. Humphry, that systematic instruction in pathology should form a part of professional education. This again is in our view a wise plan as it leaves to the teacher the fullest liberty. Pathologists of the highest distinction can thus occupy themselves with demonstrations, examinations, and lectures as they please, and we know several who particularly desire this freedom of action. Industrious students frequent the dead house. Idle ones will never learn pathology by a course of systematic lectures.

#### MIDWIFERY.

A long discussion on this subject resulted in no action. Dr. Parkes and others thought three months' instruction insufficient, especially as there was no special instruction

in diseases of women and children. When we reflect on the large part that midwifery proper plays in general practice, the dangers that attend it, the responsibilities thrown on young men, we cannot but feel there is much to be said for those who asked that students should attend 20 labours. To call it waste of time after five or six labours seems to us a speech that could only come from men who have long given up obstetric practice. Fancy a youngster who has heard a single course of lectures, and seen half a dozen natural labours, being called at distance from aid to a complicated one!

#### CHEMISTRY.

Another futile debate was whether chemistry should not be *optionally* attended before professional study. We should be sorry to injure in any way the study of this science, especially the *practical* course. It is, however, only part of a much more general question, as to what might become with advantage preliminary studies. If men enter hospitals with a fair knowledge of botany, chemistry, and other things, they are at a great advantage, and their time could be better spent than in listening to lectures adapted for those who had not made such progress. Could not teachers in such cases be allowed to promote such men to laboratory work? The teachers would be the best judges, and thus enabled to promote the true interests of their pupils.

#### THERAPEUTICS.

We spoke last week of the debate on this topic, but some correspondents seem not quite to have caught our meaning. We would urge that much progress has been made in London of late years. The lecturers in *Materia Medica* have done what they could, but the regulations are perhaps too detailed. Students have to attend in their first year, and therefore some of them are unprepared for therapeutical instruction. If two courses are to be attended, let the same lecturer give them; he could then adapt his instruction to his younger and his senior class. This is what practically one or two are trying to do, but the licensing bodies are so exacting in their regulations as to how and when a subject is to be taught, that they always feel hampered. Full liberty for teachers is our plea. With that we see the way to continued progress.

#### CLASS EXAMINATIONS.

No one objects to these, and now in most of the London schools they are in full working order; so that the debate in the Council was rather late in the day.

#### DINNER.

Most of the Councillors at the invitation of the President ran down to Cambridge for the Sunday. We hope this visit to one of the old seats of learning may not be without pleasant reminiscences.

It does, however, seem a pity that the work of the Session could not be compressed into one week, and its expense thereby diminished.

What has the Council done? It has met and talked and dined and paid itself. We are not aware that its discussions have been more beneficial to the Profession, or more practical than those that take place in the medical journals all the year round.

## Notes on Current Topics.

### The Landing of Imported Small-pox Cases.

THERE is a vague impression of the existence of some quarantine rule by which persons arriving on board ship in small-pox can be prohibited from landing; and, on the English coast, the harbour authorities exercise this questionable power with great rigour, an Irish seaman having been prevented from landing at Maryport, who was obliged to make the return voyage to Bangor while suffering under a severe attack of small-pox in the fore-castle of a small collier. The only authority which we have been enabled to discover for these proceedings is in the 52nd section of the Sanitary Act, 1866; but by that section the Privy Council is called on to make orders for treatment of the sufferers, as well as for preventing the spread of disease; but no such provisions appear to exist in the harbours of either country. In Ireland the Commissioners insist upon the Board of Guardians of the Union which contains the harbour, providing such hospital accommodation ashore as may be necessary for the treatment of persons arriving on board ship in small-pox.

### The late Dr. John Epps.

A VERY interesting series of papers are those lately published by the Nestor of Medical Journalists, Mr. J. F. Clarke, who, amongst his other recollections, has told something of the Gerrard Street Medical School and its teachers. The following in reference to the late Dr. Epps is interesting to our readers just now that we are issuing the papers in which his book was described by a *litterateur* many years ago.

“John Epps, Doctor of Medicine of the University of Edinburgh, was, I believe, the eldest son of Mr. John Epps, who some fifty years ago was noted for having a ham and beef shop in almost every part of London, and was the subject of one of the most humorous of Hudson's comic songs. Dr. Epps was a better educated man than either of his colleagues, and he had natural ability of a very high order. He was conscientious and painstaking as a lecturer, but he had an imperfect practical knowledge of either of the subjects on which he lectured; somehow or other he managed to instil a fair amount of information into his pupils. He knew more of *materia medica* than of chemistry or botany. The latter two sciences were taught by him less practically than could have been desired. He, however, ‘pegged away’ with his experiments in chemistry, and would make the students alternately prepare gases, apply the tests for poisons, &c. His laboratory was somewhat small but compact. The amount of glass destroyed on some mornings was very great—a serious loss at that time, when glass was of an enormous value compared with the present day. He, however, never lost his temper, never said an unkind word; even when the blundering pupil had smashed a dozen or more of his best glasses, the good-natured little man would say, ‘Try it again, my friend, you will get on better soon.’ He confined his teaching of botany chiefly to the system of Linnaeus. His style of lecturing was clear and attractive. He had a fund of anecdote, and was what Bacon called ‘a full man.’ He had read much, and was possessed of varied knowledge. I recollect on one occasion two or three of the students played him an innocent trick, which afforded him an opportunity of showing his readiness in resources. A bet was made that Epps would not be able to tell the name of a plant which one of the students would present to him; this wager was accepted. Accordingly H—, a Yorkshire pupil, after lecture one morning,

produced a plant, I think it was the *mercurialis perennis*, and handing it to the lecturer, said he would feel obliged by being informed of its name. Epps smiled and said, 'My friend, I should be happy to tell you, but you would derive more benefit by finding it out yourself. Do so, and if I find you correct when I come to-morrow morning I will give you my *Life of Dr. Walker*. In the meantime a name was invented—I cannot remember exactly what it was. The next morning punctually at ten—for he was always punctual—in walked the little doctor with a book under his arm. 'Well my friend,' said he addressing H—, 'have you discovered the name of the plant?' 'Yes, said H—, 'it is'—so and so. 'Very good; and here is my *Life of Dr. Walker*.' Those in the secret could scarcely refrain from a laugh, but a proper decorum was observed. H— won his wager.

"Epps had very strong political views. He was one of the school of Burdett and Cobbett; but, unlike Dermott, he never mentioned politics in his lectures, or, if he did, it was in the most cursory manner. Out of school he had no such reserve, and would speak at public meetings, or write articles of the most advanced kind. When an election was going on in his borough (Finsbury) it was his custom to have in front of his house in Great Russell street a large placard with the names of his favourite candidates emblazoned on it. He was an excellent speaker, spoke always to the point, and had a dry quiet humour, which made him a favourite with his audience. He was a man of extraordinary industry and perseverance, and never succumbed to difficulties or hard work. He was a firm believer in phrenology; Dermott was as much opposed to it. Dermott, though an energetic and practical speaker, was no match for Epps in debate. He lost his temper and blurted out offensive epithets, his wit was low and personal. Epps, on the contrary, never got out of temper; made fun of his antagonists in a good-natured way, and was usually thoroughly up in the subject he was treating.

"In person, he was below the middle height, and had something of the appearance of a quaker. He wore a broadish-brimmed hat, low down on the forehead, which was one of the finest I have ever seen. His features were regular and pleasing in expression. After the Gerrard Street School broke up, he took to the practice of Homœopathy. He died a year or two since, full of years and with the kind regrets of many of those who admired the man, whilst they regretted his 'nonconformity.'"

### Total Cost of the Poor-law System in Ireland.

THE total disbursement of Irish poor-rates for all purposes, viz., relief, medical relief, burial grounds, registration of births, deaths and marriages, and sanitary measures, was in 1869, £817,772; the levy and expenditure each making a poundage of 1s. 2½d. in the pound on the valuation. In 1870 the expenditure was £815,973, or 1s. 2½d. in the pound, and the poor-rate collected only £753,345, the difference between the expenditure and collection being, however, more than covered by the Parliamentary grant for Medical and educational purposes.

### The Crown Princess of Germany.

ON Friday morning her Imperial Highness the Crown Princess of Germany, accompanied by Count and Countess Bernstorff and Countess Theresa and Count A. Bernstorff, and attended by Count Seckendorff, visited the German Hospital, Dalston, and were received and conducted over the building by the Rev. D. Walbaun, hon. sec. and chaplain, and several members of the Hospital Committee. Her Imperial Highness evinced particular interest in many of the cases, and conversed freely with several of the inmates. Before leaving her Imperial Highness expressed

herself highly gratified with the various arrangements, and liberally subscribed to the funds of the hospital.

### Workhouse Sick Admissions in Ireland.

A GREAT decrease has taken place in the numbers admitted in sickness during the last year, as compared with the previous year. Of this decrease, amounting to 4,270, 1,823 were of cases admitted in fever, which in 1868 were 11,209; in 1869, 9,976; and in 1870, only 8,153. The relative proportion which the number admitted in sickness bears to the whole, which in 1868 were only 23 per cent., but increased in 1869 to 29 per cent., is now reduced to 27.

### Royal Visit to the London Hospital.

ON Friday morning the Emperor of Brazil visited the London Hospital, and was received by the house governor, Mr. Nixon, and Dr. Davies and Mr. Hutchinson, senior physician and surgeon, and conducted over the building, occupying about two hours in the inspection, expressing himself much pleased with the admirable arrangements of the building. In the evening the Emperor and Empress, and suite, went to the Royal Institution, Albemarle street.

### Royal College of Surgeons of England.

AT the annual meeting of the Council for the Election of Officers, held on Friday last, George Busk, Esq., F.R.S., F.L.S., of Harley street, Cavendish square, was elected president, in the room of Sir William Fergusson, Bart., F.R.S., whose term of office had expired; and Henry Hancock, Esq., surgeon to the Charing cross Hospital, and Thomas B. Curling, Esq., F.R.S., consulting surgeon to the London Hospital, were elected vice-presidents of the College for the ensuing year.

### Barth's New Portable Apparatus for Administering Oxygen Gas.

WE have lately had an opportunity at one of the large general hospitals of seeing the administration of oxygen by means of the new portable apparatus, and can report most confidently on its efficiency for the purpose for which it is designed. It is in its way quite perfect, and would serve as the easiest mode of inhaling any gas whether for physiological or therapeutical purposes.

The apparatus consists of a polished mahogany box, which is divided into two compartments, one containing the store bottle of compressed gas, the other fitted with a dilatable india-rubber bag into which the gas passes by a tube on opening a stop-cock. Another tube which opens into the bag is for the admission of atmospheric air which is propelled into the bag by means of a small pair of bellows neatly constructed. A third tube leading from the bag and terminating in an ivory mouth-piece, with stop-cock, delivers the gas to the patient.

When required the bag can be fitted with a larger tube and Clover's double-valved face-piece when the same apparatus can be used for the administration of nitrous-oxide gas if desired.

The whole can be easily carried in one hand.

THE death rate of Paris is still on the decrease, being only 872 last week, or 242 less than the preceding week.

### Scientific Disinfection.

THE Academy of Sciences of Paris appointed a commission to inquire into the best means of disinfecting. Starting with the recognised fact that infection is transmitted by living germs, spores, or animated ferments, the commission has arrived at the means apparently to be recommended in purifying infected places, linen, and furniture. In the first place, it is declared that the persons employed to disinfect generally escaped infection. In the first rank of disinfectants is placed hypoazotic acid; in its rapid action this agent is converted into neutral bioxide of azote, which immediately takes from the air of the place to be disinfected two equivalents of oxygen, in order to reconstitute itself in the form of nitrous vapour, and recover all its former energy. These transformations continue without cessation so long as any organic substance remains to be destroyed, and any free oxygen is still in the place. Unfortunately, nitrous vapour is poisonous to man, so that it can only be employed with great precautions. All orifices and fissures, door and window joints, &c., must be carefully stopped by means of strips of paper and paste. The gas having been developed in the sealed room at the end of the forty-eight hours the room is entered with the aid of the Galibert apparatus, which, by its provision of air, allows the wearer of it to penetrate into all parts of a room or ward filled with noxious gas, and remain there if necessary a quarter of an hour. The windows are opened, and the ventilation does away with all trace of the acid vapour.

This method seems a sovereign remedy, and it must not be confounded with the fumigation by means of chlorine or hypochlorites, which simply disinfect by destroying the odorous gases. A far more convenient plan, of which the efficiency has been perfectly demonstrated, is pure phenic acid, of which a given quantity is poured upon silicious powder or saw-dust of three times its own weight. The quantity used may be even greatly reduced, the floor of the apartments and the bed clothes of the patients being sprinkled daily with water containing from one-twentieth to one-thirtieth of its own weight of the acid.

Some years since, during a very hot summer, it was found impossible to purify the air of the Morgue, the quantities of gas disengaged by the corpses being so great that ventilation, chlorine, and hyperchlorates were all insufficient. It was proposed to arrest the putrefaction itself by killing the germs. Phenic acid was dissolved in a reservoir used for sprinkling the bodies; the suppression of the putrid fermentation was complete.

### The Flint Knives of Savages.

On this subject *Nature* remarks that:—

“The manner in which the Maoris use their cooking ovens suggests an explanation of the mode in which these flakes of chert came to be found in such profusion, while only a few of them show any signs of having been trimmed in order to fit them for implements. The native method of cooking is to heat the hardest stones they can find in the fire, and then placing the food to be cooked on the top, to cover the whole with leaves and earth, and through an opening to pour in water, which, coming in contact with the hot stones, causes the formation of steam by which the food is cooked. If masses of the white chert be heated and quenched with water in the manner described, the result is the formation of flakes of every variety of shape with sharp cutting edges. It is natural to suppose that when one of these flakes was found of shape convenient

for a particular purpose, such as a knife, cleaver, or spear-head, it was trimmed and dressed in the manner of a gun-flint, when the edge became defective, rather than thrown away, and favourite forms might be preserved and carried even as far as the coast. This suggested explanation of how a race advanced probably far beyond the period of such rude-looking implements might yet find it convenient to manufacture and use these, is supported by the circumstances that along with the trimmed chert flakes the Messrs Murison found finished adzes of aphanite and even jade, which shows that the hunting natives had the same implements as those which are so common among the natives at the present day, though their use is now superseded by iron.”

### Trade Frauds in Tea.

THE time-honoured process of “helping Jack” to do nothing, is being repeated with regard to a cargo of 5,000 chests of fraudulent tea which has lately reached London. The Sanitary Committee of the London Corporation reported that, having been twice defeated in their efforts to put a stop to the traffic in caterpillar’s dung, iron filings and exhausted tea-leaves, they could not advise another effort. They, therefore, called upon the President of the Board of Trade—the successor of Mr. Bright, who considers this form of roguery a mere matter of business, who informed them that they might—as the Circumlocution office says: “put it in writing,” and he would see what could be done. The case has been accordingly duly docketed, countersigned, pigeon-holed, and relegated to official oblivion, and the five thousand chests of caterpillar’s mixture is in course of ingestion by the trade-ridden public.

### Outrages under Anæsthesia.

WHEN the circumstances of the recent robbery of jewellery from the clerk of Messrs. London and Ryder, and other cases in which the crime was supposed to have been perpetrated by the agency of chloroform were under discussion, we expressed our great surprise that evidence had not been produced as to whether it was physically possible to produce insensibility in a moment, and despite the struggles of the victim. We expressed the opinion—founded on surgical experience—that, with any known anæsthetic, such an effect is impossible, and that a robbery could not be effected by such means, except after a protracted struggle, if even then. We observe by the *Philadelphia Medical Reporter*, that a Baltimore surgeon scorns the idea that men can be chloroformed while awake, insisting that no man wide-awake and sober can possibly be chloroformed without his acquiescence, unless forcibly held; and that, even if a sober man were asleep, the irritation of the air-passages caused by the chloroform would almost certainly rouse him.

The *Reporter* says: “Statements are frequently made to the effect that persons have been robbed, women outraged, and various other villainies performed, while the only excuse given to account for the opportunity was, that a handkerchief with chloroform on it was flirited in the face! This is nonsense! It cannot be done. Surgeons find that in the most susceptible cases, with the anæsthetic closely applied to the nose and mouth, some time must elapse before the party becomes unconscious. Some other theory must therefore be started to account for outrages committed when such an excuse is given.”

### Sham Degrees.

It is but a short time since we published some details of the traffic in sham medical diplomas, carried on by American *soi disant* Universities. It seems, from the following extract from a New York paper, that the trade in mock degrees is not confined to medicine, but is benevolently extended to the fine Arts. The New York paper says :

"The exposure of the American University of Philadelphia (not that of Pennsylvania) and of its bogus degrees scattered so lavishly in England and America, is attracting attention. A Baptist minister in England defends in the English *Independent* his degree of 'Doctor of Music,' saying that 'it did not come from the University of Philadelphia, but the Philadelphia University of Medicine and Surgery—an institution of great reputation, and which has been called the Edinburgh University of the United States, because of its similar reputation.' Moreover, the Baptist minister referred to adds that he 'received the degree directly from W. Paine, Esq., A.M., M.D., Dean of the Faculty, and not from any London agency; also, that the degree is the result of merit and life study.' This communication seems to have nearly satisfied our English contemporary, though still regarding a musical degree from a medical university as hardly congruous."

### American Pharmacy Legislature.

THE *Pharmaceutical Journal* notes that the Bill passed during the last session of the New York Legislature is severely criticised by the *American Journal of Pharmacy*. That journal states that, as the power of appointing the examiners is vested in the mayor, probably it will not be long before the board consists of politicians rather than of men who have the welfare of pharmacy at heart. There is no provision made for apprentices to learn under the guidance and supervision of others how to make up prescriptions; on the other hand, the salaries to be paid to the members of the examining board are so high that, after the licensing of the pharmacists at present engaged in New York, it is estimated that, if the new applications amount to one hundred annually, the licensing of every so-called drug clerk will cost the city one hundred and fifty dollars.

### Death in the Pipe.

A CORRESPONDENT of the *North British Mail*, narrates that not very long ago he paid a visit to an extensive tobacco warehouse under government locks in a large city, and saw two tobacco dealers examining a lump of foreign-manufactured tobacco, which had been stripped of its box, and which looked like cavendish tobacco of a superior quality. One of the dealers said to the other, "What d'ye think of that?" The other answered, "It looks nice. Where did it come from?" "From New York," replied he. "It's a weed that grows wild. It is not tobacco at all, they tell me." "Does it sell?" asked the other. "It seems to suit the public taste," answered he, "for we sell a good deal of it."

### Conviction of an American Abortionist.

THE assimilation of the mock-solemn phraseology of the British Judges to the plain speaking expression of

the Yankee Courts is by no means a desirable consummation. Nevertheless, we think that a little less of the milk and water might often be infused into the judgments of the Court when scoundrels insensible to mild English are the subject of the award. In the hope that, when such ruffians are brought to the block, the public may have reason to know that they are recognised as such, we quote the following judgment by Judge Bedford, of New York, on Lookup Evans, a notorious abortionist. Judge Bedford pronounced sentence as follows :

Evans, considering the overwhelming evidence against you, and the wilful perjury you committed when in the witness-box, I must express my great astonishment that twelve intelligent men should remain out all night to decide on your case. From my official experience of eight years in this court-room, I believe you to be the most consummate villain ever convicted in any court of justice. You are a professional abortionist. You have lived, thrived, and prospered in your criminal career, and have accumulated, by reason of your dark undertakings, an immense fortune. Let your conviction be a stern lesson to the many professional abortionists of this city, for on conviction they will all learn that neither their ill-gotten wealth nor their alleged great influence will be of any avail when tried in this court-room. The same penalty now about to be meted out to you will unquestionably be meted out to every other convicted professional abortionist of this city. The sentence of the Court is that you be confined in the State Prison for the term of three years and six months, the full penalty allowed by the law.

### Poison Protection.

THE second reading of Mr. Forster's Pharmacy Bill was set down for Monday evening last. The honourable gentleman, albeit not very gracious to the deputation of the Pharmaceutical Society, introduced the amendment which we sketched last week and by which he conceded as much as could have been expected. These amendments he sent to the Society's Council with a civil note. They were received, however, and cheered as an acknowledgement of defeat by the rule of thumb party. A resolution of the President's pledging the Council to accept the alterations and withdraw opposition to the Bill was moved, but an amendment hostile to the Bill was carried by a majority of one. Thus, the Society has cast away any claim they might have had to consideration and we trust Mr. Forster will trouble himself no longer with diplomacy but exercise all his influence to do justice whether the chemists and druggists like it or not. A larger issue than poison-protection is at stake, for it has now to be decided whether the Government is able to deal with an opposition dictated not by any principle, but by self-interest and carelessness for the public interest. We never doubted that Parliament will support the Government in the effort, and we do not think that the fatuous proceedings of the Society have even the prospect of success to excuse them.

THE subject for the next Actonian Prize of the Royal Institution of Great Britain is "The Theory of the Evolution of Living Things." The Prize fund is 200 guineas, which will be awarded in one prize of the full amount, or in two of 100 guineas each. Competitive Essays are to be sent in before the end of June, 1872.

### Testimonial of Respect.

THE inhabitants of Brighton are bestirring themselves to present to Mr. J. Cordy Burrows, J.P., F.R.C.S., &c., who has practised in their town for many years, a substantial mark of their esteem. Already over £600 has been collected, and more is coming in. We understand the testimonial is likely to take the form of a carriage and pair and a service of plate. We heartily wish our *confreere* length of days to enjoy this reward of his labours.

DR. BALL, the senior member for Dublin University, is recovering from his recent severe illness.

DR. MINTER, late of the Royal yacht, has been nominated Deputy Inspector of Hospitals and Fleets at Malta.

A RUSSIAN lady, Marie Bokowa, who, we understand, rendered valuable service in the Heircourt Hospital during the war, has recently taken M.D. Zurich.

A COMPETITIVE examination for the admission of Assistant-Surgeons to the Royal Navy will take place at the London University on the 9th of August and following days.

A FEW days since a little child of Mr. Meggit, surgeon, of Scarborough, managed to get into her father's surgery, and drank a small quantity of nitrate of mercury. Death resulted in a few hours.

THE Fishmongers' Company of London have made a donation of £50 to the National Sanatorium for Consumption and Diseases of the Chest at Bournemouth. The Queen has also contributed £100 to the same fund.

MR. A. KEMPE, surgeon to the Devon and Exeter Hospital, having resigned, was at a late meeting of the governors elected consulting surgeon and honorary governor. Mr. W. Caird succeeds him.

OWING to the death of Mr. Damville, Mr. Bowring becomes full Surgeon to the Manchester Royal Infirmary. Owing to a decision of the Board some years ago not to choose any more surgeons until those on the staff had all arrived at the position of full surgeon in rotation, his promotion leaves no vacancy.

THE iron crown of the second class has been bestowed on Dr. Freidrichs, of Berlin. M. Ricord and M. Demaquet have also been promoted to the ranks of Grand Officer and Commander respectively. Our readers will be glad to note the advancement of our profession as a reward for real services during the war.

THERE was a very large and aristocratic gathering at Greenwich on Saturday at a dinner given to the members of the Red Cross Society, whose devoted services during the late war have been so often and deservedly commented upon. Amongst the company present were several members of the profession, and the health of the "medical officers coupled with the names of Dr. McCormac and Mr. Farley," was drunk with great enthusiasm.

THE mortality from small-pox has greatly diminished lately. In London, from 235 the deaths have sunk to 164, the largest increase being in the east, though well marked in all districts. The greatest mortality last week was in the north and south. No more patients will be admitted to the north and south, but in case of need will be accommodated at Hampstead. It still continues undiminished in the provinces, the annual mortality at Southampton, Weymouth, and Grimsby for the last few weeks being equal to 14, 21, and 24 respectively. There are numerous new cases weekly in Liverpool. House-to-house visitation have been instituted in Manchester, and 5,000 children been found un-vaccinated. It is slightly on the increase in Ireland.

DR. MEDLICOTT, an American physician, stands accused of the murder of a Mr. Ruth. Dr. Medlicott, who had been regarded as an admirer of Mrs. Ruth, was with her husband alone on the night before the morning of his death. Ruth left a note in which he said he had taken a powder given him by Medlicott, and analysis of his stomach betrayed the presence of poison. But another complication is now added to the plot of this tragedy. Mrs. Medlicott had died suddenly some time before, and there were not wanting people who regarded her sudden taking off with suspicion. Her husband's good professional standing, however, his unstained record before the world, and his high position in the church of which he is a member, prevented the affair from undergoing close scrutiny. The body of Mrs. Medlicott has been exhumed, since the death of Ruth, and the stomach examined; and poison has been found therein. Some doubts exist as to the nature of the poison found in Ruth's stomach; and the evidence that connects Medlicott with the administration of the drugs is yet purely circumstantial.

## Transactions of Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 27TH, 1871.

MR. CURLING, F.R.S., PRESIDENT, IN THE CHAIR.

THE Report from the Committee appointed to examine Mr. Hutchinson's cases of Vaccino-Syphilis was read.

ON DEXTRAL PRE-EMINENCE.

By WILLIAM OGLE, M.D.

Assistant-Physician to St. George's Hospital.

1. After a very brief account of the chief explanations which have been given of right-handedness, the author advances numerous arguments against the most generally accepted doctrine that it is based on conventional agreement, enforced by educational influence, and has no natural foundation in our physical conformation. Of these arguments the following are the chief:—The preferential use of one side is not limited to the arm, but extends to the leg, which is not subjected to education as the arm. The tendency to use one side preferentially manifests itself before education begins, and often persists in spite of the efforts made to overcome it. Left-handedness resembles many physical malformations in being hereditary, in running in families, and in attaching itself rather to the male sex than to the female. Statistics are given of its relative frequency in the two sexes. Men are not the only animals with a tendency to use one side preferentially. The author gives an account of his observations in this matter on monkeys and on parrots.

2. Having shown that there must be some one or other structural foundation for right handedness, the author next considers what this may be. He shows that in right-handed persons the left hemisphere is proved to be pre-eminent over the right by its lodging the faculties concerned in speech, &c.; and that in left-handed persons the right hemisphere has a similar superiority. This latter statement, the probability of which was suggested by the author several years ago (St. George's Hospital Reports, vol. ii., 1867), is supported by three cases of aphasia in left-handed persons, accompanied by left hemiplegia, which the author has himself seen and a fourth recorded by Dr. Jackson. So that right and left-handedness would seem doubtless to depend on a natural predominance of the left and of the right hemispheres respectively.

3. Inquiry is then made whether any structural differences between the two hemispheres can be detected; and it is shown that while the left is the more complex in right-handed persons, the contrary is the case in left-handed individuals. This latter statement is based on the examination of the brain in two left-handed subjects. The specimens were exhibited, and also tracings of them by Dr. Broadbent.

4. Finally, the question is considered—What is the cause of the greater development, as a rule of the left hemisphere? It is argued that it depends probably on the left hemisphere receiving a freer supply of blood than the right one. The results of the author's observations as to the relative sizes of the arteries on the two sides of the neck are given; from which it appears that the left arteries arc, as a rule, slightly larger than the right ones. It is also shown that, independently of the size of the vessels, the stream of blood is less hindered on the left side than on the right. Lastly, it is shown that this explanation is consistent with, and corroborated by, the peculiarities of the cerebral blood supply in those other animals, which, like man, manifest a tendency to use one side preferentially to the other—such as parrots.

Mr. SAVORY, in expressing his admiration of the very able paper presented to the Society by Dr. Ogle, said that he must also express surprise that the question of dextral pre-eminence had been treated with reference to the extremities only. We found a corresponding departure from symmetry in every part of the body. Every microscopist knew that he had a favourite eye; and it was always more easy to wink with one eyelid than with the other. The septum nasi was not in the median line; and the power of smell of the larger nostril was superior to that of the other. Mastication, without any reference to decayed or painful teeth, was performed usually on only one side of the mouth. Every nursing woman suckled her child more at one breast than at the other; and almost everyone slept constantly upon the same side. With regard to the complexity of the cerebral structure, he should have liked to hear something about the ganglia at the base of the brain, the so-called sensory ganglia, as well as about the hemispheres; although he admitted the great difficulty of such an investigation. In respect of the blood supply, he thought that the general teaching of physiology was opposed to considering this as a cause of growth, and led us to regard it rather as an effect of nutrition. The well-known transplantation of a cock's spur, by Hunter, as well as the periodical activity of certain organs, seemed to point in this direction.

Dr. CHARLTON BASTIAN, like Mr. Savory, felt doubtful of the correctness of Dr. Ogle's suggestion that greater blood-supply might be a cause of increased growth. With regard to the general question, he thought the view taken about the reason of dextral pre-eminence would depend upon whether we regarded man as the result of a single creative act, or of a complex process of evolution. He had lately made a post-mortem examination of the head of a man who had in his lifetime been remarkable for great intellectual power, and who had been from childhood blind of the right eye. In that case there was a very remarkable excess of size of the right over the left hemisphere, the former measuring longitudinally, over the vertex, five-eighths of an inch more than the latter. Four or five years ago he had made and published a series of observations on the specific gravity of the brain-substance, and had satisfied himself that the grey matter of the left hemisphere was specifically heavier than that of the right. For this he was at the time unable to suggest any explanation; but now, coupling it with the fact that the grey matter of the posterior lobes is specifically heavier than that of the anterior lobes, on account of the greater admixture of white communicating tissue in the former, he thought that the greater weight of the grey matter of the left hemisphere might also possibly be

due to the larger proportion of communicating fibres required by its greater complexity of structure and greater functional activity.

Mr. BRUDENELL CARTER suggested that examinations of the brains of adults who had undergone amputation of an upper extremity in early life might throw important light upon the question.

The PRESIDENT, on account of the lateness of the hour, and of the number of papers still to be read, then stopped the discussion, and called upon Dr. Ogle to reply.

Dr. OGLE, after thanking the Society for the reception accorded to his paper, said that he had not been unmindful of the desirableness of investigating the condition of the sensory ganglia, but that the difficulties in the way of doing so had as yet been too considerable to be overcome. As regarded the question of blood-supply, he had plainly stated in his paper that it might be either a cause or a consequence of increased growth, and he thought the balance of evidence was in favour of the former supposition. In very young rabbits, after section of the vaso-motor nerve in the neck, he had observed hypertrophy of the ear on the side operated upon, attended, in some instances, by increased growth of hair. He acknowledged the importance of Dr. Bastian's observations about the different specific gravities of different parts of the brain, and thought that these observations told in favour of his argument.

ON THE INDICATIONS FOR OPERATIVE TREATMENT, AND ON A NEW OPERATION "KERATECTOMY," AFTER SEVERE INJURIES OF THE EYEBALL; WITH CASES.

By W. SPENCER WATSON, F.R.C.S., ETC.

Surgeon to the Royal South London and to the Central London Ophthalmic Hospitals.

In the case of penetrating wounds, the occurrence of glaucomatous symptoms is shown to be the most urgent indication for operative treatment—viz., either linear extraction, or iridectomy. At a later stage, after the subsidence of the acute symptoms, iridectomy may be required, or the removal of the cataract indicated, and these operations are most likely to be successful when all signs of active congestion have disappeared. Cases in illustration are given. The prospect of the complication of sympathetic ophthalmia is always possible when the stage of congestion, with pain and photophobia, is much prolonged, and whenever a foreign body is left in the injured eye. Under these circumstances, the removal of the injured eye is sometimes necessary; but if constitutional treatment can be properly carried out, the removal of the injured eye may be postponed or altogether averted. A case in illustration is here given.

In traumatic and idiopathic cases of suppurative ophthalmitis the operation of keratectomy is proposed, and in one case has been performed successfully by the author. Its object is to establish a fistulous opening in the cornea, through which the morbid products of the inflammation may escape freely, until such a time has elapsed that the tissues may have recovered. It is suggested that in some cases of threatened suppurative ophthalmitis, keratectomy might prevent the anticipated mischief.

THE MODIFICATIONS PRODUCED ON THE TEMPERATURE OF THE BODY BY THE LOCAL APPLICATION OF COLD AND HEAT.

By FREDERICK BARHAM NUNNELEY, M.D.,

Assistant-Physician to the City of London Hospital for Diseases of the Chest.

Experiments, detailed in the paper have yielded the following results:—

1. That immersion of one extremity in iced water did not cause any alteration in the temperature of the other extremities or the body generally, unless the subject of experiment was in a state of more or less nervous exhaustion or there was decided coolness of the surrounding air, when a fall of temperature occurred.

2. That a slight rise of temperature in the body generally, and a more considerable one in the extremities, followed immersion of a hand or foot in water hotter than the blood, amounting under the tongue to about 1 deg. F., and in the extremities from 1 to 3 degs. F., above the normal standard.

3. And that if at this time any one of the extremities was put into cold water, a fall of temperature below the normal, slightly marked in the body generally, and much more so in the extremities, very shortly commenced. If the hand or foot

was now withdrawn from the water, reaction became established, and the natural temperature was slowly attained.

Such results would appear to show that, for cold to act locally, a disturbance of the conditions which maintain the normal balance of temperature is necessary first of all—such as is caused by undue heat; and suggest the idea that these variations of temperature may be regarded, in many respects, as parallel to those attending a slight rigor, and that they are not always the result of reflex agency.

ON A SIMPLE METHOD OF REMOVING SILVER WIRE WHEN EMPLOYED IN CASES OF UNUNITED FRACTURE.

By FRANCIS MASON, F.R.C.S.,  
Assistant-Surgeon to St. Thomas's Hospital.

The object of the paper is to describe a plan of fastening the broken fragments with a needle and a loop of wire so arranged that in withdrawing the needle the loop of wire is released, and thus may be removed without pain to the patient and without injuring the bone or soft parts.

At the conclusion of the meeting, the president drew the attention of the fellows to the change in the times of assembling which had been adopted at the last annual meeting, and which would commence with the next session—namely, that the first meeting of the Society would be on the second Tuesday in October instead of in November. He further mentioned that, to allow of the alterations connected with the Society's meeting-room being previously carried out, the library would be closed during the months of August and September.

CURRENT LITERATURE.

MESSRS BAILLIERE have brought out a practical guide to Aix, by the physician to the bathing establishment\* of that delightful retreat in Savoy. This pamphlet contains some very good advice to those about to visit Aix, and if the English is of the kind that may be called Frenchman's English, it will not be misunderstood by any one who has travelled abroad for only a short time.

MR. HUNT'S little book on the skin† has reached a ninth edition. The author's views are so well known, that this announcement will suffice. We are glad to see he warns anyone outside the profession into whose hands it may fall, not to tamper with arsenical or mercurial preparations, "which ought never to be made use of excepting under the watchful eye of a medical practitioner."

THE HALF YEARLY ABSTRACT.‡

WE have also received the half-yearly volume so familiar to us under the editorship of the late Dr. Rankin, and which is now edited by Dr. Domett Stone, who keeps it up to the level it had attained. We observe a number of the contributions to our own pages are here collected with those of our contemporaries—an effort being made to make the half-yearly volume practical.

FENWICK'S DIAGNOSIS.§

WE certainly owe a word of recognition to the second edition of Dr. Fenwick's able work, inasmuch as a suggestion of our own made when commending the first edition has been adopted, viz., to add a chapter on the diagnosis of diseases of the skin, which has been done in a manner equal to the other parts of this handy little book. We should also say that the author has carefully revised the book throughout, so that it is fully up to the mark in every respect—quite a boon to clinical students.

PROCEEDINGS OF THE  
GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

SESSION 1871.

MONDAY, JULY 10TH.

THE Report of the Committee on Education, which we printed last week, was somewhat modified. The latter portion of the amended report says some suggestions require an opinion, while as to others, they should be left in abeyance.

Of the former kind, there are some of considerable importance:—

1st. The separation of teaching of Pharmacy and Therapeutics, the former being made an early, and the latter a later course of the Curriculum.

It seems desirable that the instruction in Pharmacy should be separated from that in Therapeutics, and that the former should be obtained at an early, and the latter at a later period of the Professional Curriculum.

So, also, it will be for consideration how far practical instruction in drugs and pharmaceutical preparations might not be substituted for formal lectures. In the last two sessions a plan of this kind has been carried on in Aberdeen.

2nd. The recommendation that Pathological Anatomy should be made a separate course has not been carried out in all cases, but several of the Licensing Bodies have endeavoured to meet it by requiring a certificate of attendance, and of practical instruction in the Dead House.

It is desirable that systematic instruction in Pathological Anatomy should form a part of Professional Education.

3rd. The Committee on Education strongly advised the enforcement of more regular Class Examinations. Certain of the Licensing Bodies have ordered that all Students shall produce evidence of having undergone these Examinations, and it is desirable that all the Licensing Bodies should issue Regulations that Class Examinations shall form a necessary part of every course of instruction.

The other points raised in the Education Report of 1869, and which we advise should not be discussed at present, are—the length of the sessions, the method of teaching Chemistry, and the application of Chemistry to Physiology and Pathology, the teaching of Minute Anatomy, and the definition of the areas of Instruction and of Examination.

The Council will doubtless remember that the Education Report of 1869 strongly recommend the formation of Conjoint Examining Boards, so as to reduce the number of Examinations for Licences to practise, and to make each Licence a Qualification in both Medicine and Surgery; that the Council authorised circulars to the Licensing Bodies in this sense, and that in the autumn of 1869 various conferences took place between some of the Licensing Bodies, and replies were received from many of them favourable to the proposed combinations. Subsequently the action of the Government in introducing a Bill suspended all negotiations of the kind.

The withdrawal of that Bill makes it desirable that these negotiations be resumed.

It might indeed be argued that the willingness of the Licensing Bodies to improve their Examinations, and the fact that they really have improved them, renders it less necessary to revive the plan of a uniform Examination for each division of the Kingdom. But a moment's reflection will show that the proposal is still necessary.

The independent examinations for Licences being as numerous as ever, the risk of inequality of standard in different parts of the Kingdom still obtains.

This inequality may doubtless be to a certain degree corrected by more constant and systematic visitations, but the only effectual remedy in the opinion of the Council is the consolidation of Examinations.

In a Resolution, which was carried by seventeen votes against one on the 26th of February, 1870, the Council decided that it was of opinion that a joint Examining Board should be formed in each division of the Kingdom. It is, therefore, desirable that the Council should address a letter to each Licensing Body, transmitting a copy of the Resolution of the 26th February, 1870, and urging that arrangements for the formation of the Boards shall be undertaken without delay.

(Signed) E. A. PARKES, *Chairman.*

Moved by Dr. PARKES; Seconded by Dr. ANDREW WOOD; and agreed to: "That the Report of the Committee on Professional Education as now Amended be received and adopted, and that copies be sent to the several Licensing Bodies for their consideration."

2. Moved by Dr. PARKES and seconded by Dr. ANDREW WOOD: "That in case the arrangements for Conjoint Examining Boards are not completed in each Division of the Kingdom by the close of the year, in accordance with the recommendations of the Council on the subject, the Executive Committee shall be authorised to seek an interview with the Lord President of the Privy Council and to urge upon him the desirability of such Medical Legislation in the Session of 1872 as may carry out the object the General Medical Council had in view, in passing the Resolutions of the 26th and 28th February, 1870, and of the 7th July, 1871."

3. Amendment moved by Dr. ALEXANDER WOOD, and seconded by Dr. STORRAR: "That a Meeting of the General Medical Council be held early in 1872, to receive the proposals of the Bodies for Conjoint Examinations, and to consider whether any, and what steps should be taken to carry out the Resolutions of the Council in favour of such combinations."

The Amendment was carried, and having been put as a Substantive Motion was again carried.

The Report of the Committee on the Registration of Medical Students, and the Returns from the Bodies in Schedule (A) of Professional Examinations and their results were read and referred to the Executive Committee.

The following Report of the Committee on the Visitation of Examinations was read, and referred to the next Meeting of the Medical Council.

Some votes of thanks, &c., concluded the Session.

#### HAVILAND'S GEOGRAPHY OF DISEASE.

On the 10th inst., Baron Corvisart, by direction of his Imperial Majesty, the Emperor Napoleon, visited the author of the above work at his residence, and inspected his maps on "The Geographical Distribution of Disease." This week his Majesty, by letter to Mr. Haviland, intimated his desire to become a subscriber to the work; requesting that each part should be forwarded to him by Messieurs Baillièrè, Tindall, and Cox. We rejoice at this distinguished recognition of the services of one of our *confères*, whose arduous labours will doubtless be sweetened thereby.

#### THE CONJOINT EXAMINING BOARD IN LONDON.

An important statement on this subject was made to the Medical Council by Dr. Bennett on Friday week, from which we learn that the College of Surgeons and Physicians have been obliged to content themselves with a mutual arrangement, which will not include either the Universities or the Apothecaries' Hall. Dr. Bennett stated that the latter body had been prevented by their Act of Parliament from co-operating as they desired to do. Certain clauses have been included in the scheme to enable the Universities to co-operate if they wish; but the fundamental basis of the scheme is, that no Body which is a party to it shall give any qualification *per se*, except an honorary degree. The examiners are to be appointed by a Committee of Reference, which is to be formed of four medical members from the College of Physicians, four surgical from the College of Surgeons, and one medical and one surgical from each co-operative University.

On the following Friday, Dr. Parkes moved that every Licensing Body receive a copy of a resolution in favour of

Conjoint examinations, which had been adopted by the Council last year, and that the Licensing Bodies should be urged, without further delay, to make arrangements for the formation of such Boards.

Sir Dominic Corrigan distinguished himself by standing alone in opposing the proposal which the representatives of Cambridge, Dublin and Durham Universities cordially supported.

We observe with surprise that the Council received no information, as to the state of the question in Ireland, from Mr. Hargreave, the representative of the Irish College of Surgeons.

It should be known that that body has always been most anxious to comply with the suggestion of the Medical Council, and on three occasions made overtures to the Irish College of Physicians and Apothecaries' Hall for the initiation of such organisation. The opposition to any such movement was led by Sir Dominic Corrigan, and the College of Surgeons was at length obliged to abandon the effort.

Sir Dominic Corrigan stated to the Medical Council that "the plan could not be carried out in Ireland." We believe such an observation to be altogether incorrect, and, as far as we know nothing stops the way but exorbitant financial demands on the part of the College of Physicians.

#### QUALIFICATION IN MIDWIFERY.

An effort was made last week by a party in the Medical Council to extend somewhat the study of midwifery. Dr. Parkes wished that attendance in twenty labours should be required, but that resolution and two amendments which demanded an increased qualification in midwifery and diseases of women were all rejected, so that the requirements of Licensing Bodies in this respect will not be altered.

#### OBITUARY.

##### JOSEPH GOODALE LANSDOWN.

CONSULTING SURGEON OF BRISTOL GENERAL HOSPITAL.

THIS gentleman died at Bristol on the 6th inst., aged sixty-seven. Mr. Lansdown was for many years surgeon to Bristol General Hospital, and on his retirement in 1861, he was appointed consulting surgeon.

##### THE LATE DR. TANNER.

WE have to announce the death of a very popular London physician, who has achieved no inconsiderable reputation both in his profession and as a *littérateur*—viz.: the late Dr. Thomas Hawkes Tanner, F.L.S., who has but recently passed from amongst us at the age of forty-six. He had been out of health for some time, and there is no doubt but that his death was caused by the effect of overwork on the brain. His father was secretary to the Army Medical Board. Dr. Tanner was educated at the Charterhouse, at which period of his life he met with an accident, which caused a slight lameness all his life. He entered King's College in 1843, in 1849 took M.R.C.S.E., and the same year graduated in medicine at St. Andrews. After being resident physician in King's College Hospital, he began practice in Charlotte street in 1861, being about the same time appointed physician to the Farringdon Dispensary. In 1850, he took M.R.C.P.E., and also lectured for a little time on Forensic Medicine at

the Westminster Hospital. He leaves a wife and family to lament his untimely loss. He was successful in his profession, above many, and was also known in medical journalism.

### THE LATE DR. HEWITT.

THE late Dr. Samuel M. Hewitt, although his death occurred when only twenty-five, had already reached considerable eminence among the younger Dublin physicians. He commenced as demonstrator of anatomy in the school of the College of Surgeons, and his election as physician to the City of Dublin Hospital was not contested. He was most attentive to the patients in the hospital under his care, and whilst amongst them he caught typhus fever, of which he died. The May number of the *Dublin Quarterly Journal of Medicine*, contains an able paper from his pen. He was followed to his grave by all his colleagues, about a hundred students, and many distinguished medical men.

### THE LATE MR. A. W. DUMVILLE.

THE profession loses one of its most skilful and practised surgeons in the person of the late Mr. Arthur William Dumville, F.R.C.S., of Manchester, who died on the 8th inst., aged fifty-two. He was for many years lecturer on surgery at the Manchester School of Medicine, and surgeon to the infirmary. He was unusually able as a clinical teacher. As an example of his skill, it may be remarked that he used to perform Syme's operation of external urethrotomy, without a guide, with a dexterity, we make bold to say, unsurpassed by any modern surgeon. He wrote but little, so it is probable that he will not be remembered so well and widely as he deserves to be.

### DR. DUNDAS.

THE profession loses another distinguished member in the person of the late Dr. Robert Dundas, who died at his residence in Gloucester place, London, on the 25th ult., in his eightieth year, the cause of death being exhaustion consequent on a chronic attack of sciatica. He was born in Ireland towards the end of last century, and entered the army (medical service) at an early age. He served in the Peninsular, and at the siege of Orleans 1815, afterwards settling at Bahia in Brazil, where he was medical superintendent of the British hospital for twenty-three years with great credit. His health failing, he resigned and returned to Europe, but as he was naturally too active to lead a life of leisure and let his abilities rust away, he settled in practice at Liverpool, when he was also appointed physician to the Northern hospital. In 1852, he published "Sketches of Brazil," in which he strongly advocated the dogma that intermittent fever is *not* the result of malaria, but may be generated by electrical, thermometric, and morbid hygienic conditions apart from the action of marsh miasmata. He also adduced considerable evidence to prove the possibility of treating long continued fever by the use of quinine. In 1854, he left Liverpool and settled at London, where he remained until the day of his death. He was a stern, intellectual, firm, upright, conscientious, unflinching, affectionate, and sympathetic man, and had great influence over all with whom he met.

## Medical News.

**A Valuable Precaution.**—When we regard the number of invalids who are suffering from disorders of the digestive organs arising from carelessness in eating and drinking, we are inclined to wish that the old times had returned, when phy-

sicians sat by their wealthy clients to warn them against excess, and to decide upon what was wholesome. Chaucer reads us a good lesson when he recounts the obstinacy of Henry I., who died from eating lampreys:—"He wylled of a lampreye to ete, But hys leches hym verbede, vor it was a fetele mete."—*Food Journal*.

**Kangaroo Soup.**—Ever since European colonies were founded in Australia, the excellence of the flesh of the kangaroo has been universally recognised by the colonists. The tail, which is very muscular or fleshy, is regarded as an especial luxury, and kangaroo-tail soup is probably one of the best kinds of soup ever placed upon the table in any country. It comes to this country in a perfectly fresh state, in tins, like Australian beef and mutton, and is sold under the name of Kangaroo venison.—*Food Journal*.

**Presentation.**—Dr. Johnston, of Montrose, on retiring from practice, after having been nearly thirty-five years engaged in it, has been presented by his friends and patients with a very handsome testimonial in the shape of a silver service.

**The End of the Zouave Jacob.**—It may be remembered that some time ago a certain Zouave Jacob gained great notoriety in Paris by professing to cure all diseases with the simple touch of his finger, and that thousands of the most civilised people in the world patronised him. The *Figaro* tells what has become of this arch-humbler. He joined the army of the Loire, and was shot on November 28th, by his own comrades for treachery and espionage—truly a worthy end to such a career.—*Globe's Correspondent*.

**Testimonial to Professor Halford.**—The *Melbourne Argus* of May 20th, says that Professor Halford has been presented with a testimonial, consisting of a handsomely bound book and a purse of 120 sovereigns, as a recognition of the merits of his method of treating cases of snake-bite by the injection of ammonia.

**Ricord and Demarquay.**—It is intended to entertain at a complimentary banquet MM. Ricord and Demarquay, who are now in London. Sir W. Fergusson, Bart., F.R.S., will preside. The committee of arrangement includes Mr. Busk, Mr. Paget, Mr. Hilton, Mr. Curling, Mr. Hancock, Mr. Erichsen, and Sir Henry Thompson.

**British Medical Association.**—The local committee appointed by "The Three Towns," Plymouth, Devonport, and Stonehouse, to prepare for the annual meeting of the British Medical Association in 1871, have succeeded in obtaining the cordial co-operation and assistance of the civil and military authorities, so that every facility will be furnished them for inspecting the naval and military arsenal; Her Majesty's ships of war in the Hamoaze and Plymouth Sound; Her Majesty's dockyards at Devonport and Keyham; the Royal William victualling yard, and the naval and military hospitals in Stonehouse; the Breakwater and its lighthouse; the Eddy-stone lighthouse; the Plymouth Citadel, the Hoe, and the forts recently erected within a radius of five miles.

**Sanitary Condition of London.**—At the Court of Sewers last week, Dr. Letheby reported that during the past fortnight 539 houses had been examined, of which 60 required sanitary improvement in various particulars. 99 bakehouses and 69 vessels had on inspection been found to be in a good condition. 1,428 articles of clothing had been disinfected at the City mortuary. At the markets and slaughter-houses 3,266 lbs. of meat had been seized as unfit for human food and destroyed in the usual manner. It consisted of 31 sheep, 7 pigs, 4 calves, 13 quarters of beef, and 4 joints of meat. 43 deaths and 72 births had in the course of the fortnight been registered in the City. The mortality returns were much below the average (86) for the corresponding period of the last ten years. 14 of the deaths were among children of less than five years of age, and 11 among persons of sixty and upwards. The chief causes were:—Phthisis, 5; mesenteric disease, 4; hydrocephalus, 2; pneumonia, 4; bronchitis, 3; small-pox, 1; croup, 1; whooping-cough, 1; and scarlet fever, 1; making 11 deaths from tubercular disease, 5 from inflammatory affection of the lungs, and 4 from diseases of a zymotic character. The returns indicated a satisfactory condition of the public health.

**Small-pox in Southampton.**—The deaths from small-pox seem now to be sensibly on the decrease weekly. Sixteen during the fortnight ending Saturday, as compared with twenty-six for the two weeks preceding.

**A new cure for Cancer.**—A remarkable plant is reported from Ecuador, the juice of which is said to be a certain cure for cancer; Dr. Keene, of Washington, pronounces it a most valuable discovery for the medical faculty of the world. We should think so!

**The Son of Dr. Jenner, and nephew of the discoverer of vaccination,** is now through adverse circumstances, living in a very small cottage with hardly the necessaries of life.

**Plants from Morocco.**—Dr. Hooker, director of the Royal Botanical Gardens at Kew, has returned from Morocco with a large collection of new and rare plants.

NOTICES TO CORRESPONDENTS.

**DR. EDWARDS CRISP.**—We cannot re-open the question.  
**DR. LETHBY.**—Proof returned too late for insertion.  
**HINTS HOW TO MAKE VACCINATION MORE EFFICACIOUS.**—We have received the concluding remarks from Mr. Robert Hanslip Sers, together with a woodcut illustration of a proposed new Vaccination Sleyee. Our correspondent is such an earnest worker, and has proved himself so thoroughly practical in his suggestions, that we shall give the earliest insertion to his paper, for which we tender him our thanks.  
 The following communications are in type, and will appear, if possible, in our next:  
**Dr. Lethby,** “On the Purification of Water.” (2nd part).  
**Dr. Morgan, F.R.C.S.,** “On the Nature of the Venereal Poison, as Illustrated by Direct Experiment and Observation.” Illustrated with diagrams printed on toned paper.  
**Professor Sorby, F.R.S.,** “On Blood-Stains.”

VACANCIES.

**Taunton Union:** Medical Officer for the Churchstanton District. Salary £52, with extra fees for Midwifery. (See advt).  
**Birmingham Free Hospital for Sick Children.** Resident Medical Officer. Salary £60 per annum with board.  
**Bradford Infirmary.** Physician. Honorary.  
**Seaman’s Hospital (Dreadnought).** A House-Physician and a House-Surgeon.  
**St. George’s Hospital.** Medical School Teacher of Physiological Chemistry.  
**Warwick County Lunatic Asylum.** Assistant Medical Officer. Salary £100, with board and residence.  
**Huddersfield Infirmary.** House-Surgeon. Salary £60, with board.

APPOINTMENTS.

**CAIRD, T. W., M.R.C.S.,** Surgeon to the Devon and Exeter Hospital.  
**CAMPBELL, W. M., M.B.,** Junior House-Surgeon to the Northern Hospital, Liverpool.  
**DONOVAN, D. D.,** Physician to the Cork General Dispensary.  
**DUKE, B., M.R.C.S.,** Resident House-Surgeon to the Brighton Dispensary.  
**EDWARDS, H. J., M.R.C.S.,** Surgeon to the Teignmouth Infirmary.  
**FIRMAN, Mr. C. G.,** Assistant-Surgeon to the 1st Kent Artillery Volunteers.  
**GRIFFIN, Mr. I., M.R.C.S.,** Ensign in the 3rd Oxon Rifle Corps.  
**KEMPE, A., F.R.C.S.,** Consulting Surgeon to the Devon Hospital.  
**LEE, E. S., M.R.C.S.E.,** House-Surgeon to the Leicester Infirmary.  
**NICHOLSON, Dr. D.,** Assistant Medical Officer to H.M.’s Invalid Prison at Woking.  
**ROPE, H. J., M.R.C.S.E.,** Resident House-Surgeon to the Salop Infirmary, Shrewsbury.  
**TATHAM, G., M.R.C.S.E., J.P.,** Vice-President of the Sussex and Brighton and Medico-Chirurgical Society.  
**TORRY, J. C., M.D., M.R.C.P.L.,** Physician to the Infirmary for Consumption, &c., Margaret street, Cavendish square, W.

Marriages.

**DE LISLE—BLAIR.**—On the 11th inst., at the Church of St. Peter Port, Island of Guernsey, Frederick Irving De Lisle, L.R.C.P., &c., to Lucy Caroline Josephine, daughter of the late Lt.-Col. Blair, C.B., 10th Bengal Cavalry.  
**HASLEWOOD—ASHTON.**—On the 5th inst., at Castleton Church, Albert O. Haslewood, Surgeon, of Castleton, Derbyshire, to Mary How, younger daughter of the late Robert How Ashton, Esq., of Castleton.  
**SHAW—DONKIN.**—On the 11th inst., at Ryhope Church, Charles Shaw, M.D., L.R.C.S.Ed., to Janet Donkin, younger daughter of the late Robt. Donkin, Esq., of North Shields.

Deaths.

**DUMVILLE.**—On the 8th inst., Arthur W. Dumville, F.R.C.S.E., of Ardwick green, Manchester, aged 58.  
**HESTER.**—On the 1st of May, at Wangaratta, Australia, J. Hester, M.D., second son of J. T. Hester, F.R.C.S.E., of Hastings.  
**HEMPHILL.**—On 7th July, at his Father’s residence, Wheatfield, Myroe, James Patton Hemphill, A.M., M.D.  
**MAY.**—On the 5th inst., Willoughby May, L.R.C.P.Ed., M.R.C.S.E., of Teignmouth, aged 31.  
**MOSTYN.**—On the 6th inst., at Alpha House, Fairview, Dub’in, T. Mostyn, Deputy Inspector-General, late of the 27th Regiment.  
**RUSSEL.**—On the 5th inst., Robt. C. Russel, L.R.C.S.Ed., of New Machar, Aberdeenshire, aged 67.

Advertisements.

GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, BRIDGE STREET, MANCHESTER.

The Office of RESIDENT MEDICAL OFFICER to the above Institution will become vacant on August 14th. Candidates for the Office must be on the “Medical Register” and unmarried. The salary is £100 per annum and board. Applications addressed to the Hospital, Bridge Street, must be sent up to July 22nd.

ST. THOMAS’S HOSPITAL MEDICAL AND SURGICAL COLLEGE.

THE ACADEMICAL SESSION for 1871 and 1872 will commence on MONDAY, the 2nd OCTOBER, in the new Buildings on the Albert Embankment, Westminster Bridge.

To enter, and for further particulars, apply to R. G. WHITFIELD, Medical Secretary, at the Manor House, St. Thomas’s Hospital, Newington, Surrey, S.E.

NAVAL MEDICAL DEPARTMENT, ADMIRALTY, SOMERSET HOUSE, 1st July, 1871.

NOTICE OF EXAMINATION FOR ENTRY OF ASSISTANT-SURGEONS IN THE ROYAL NAVY.

NOTICE IS HEREBY GIVEN that a COMPETITIVE EXAMINATION for the Admission of Assistant-Surgeons into the Royal Navy will take place at the University of London, Burlington Gardens, on Wednesday, 9th August, 1871, and following days, at 10 o’clock.

Candidates must present themselves at this Department on Monday, 7th August, 1871, bringing with them the various Certificates of Qualifications specified in the Regulations of the 24th June, 1871, when, should they be found in all respects eligible, they will be permitted to appear for Examination.

A. ARMSTRONG, Director-General.

**TAUNTON UNION.**—The Board of Guardians of this Union are desirous of receiving Applications for the Appointment of a MEDICAL OFFICER (duly qualified) for the Churchstanton District, comprising the parishes of Churchstanton and Otterford.

Area—7,399 acres; population, 1,437; salary, £52.  
 This salary includes all extra fees of every kind, except 10s. for each case of Midwifery which the Medical Officer shall attend, if lawfully authorised; he will, if duly qualified, be appointed under the Vaccination Act of 1867, with the fees prescribed by the said Act; and he will be entitled to 2s. 6d. per case for each quarterly visit to Lunatic Paupers resident in the district.

Information as to the district, duties, &c., may be had on application to me. Testimonials of Qualification, &c., to be left at my office, on or before Friday, the 20th July, instant. The election will be proceeded with on Thursday, 27th July, instant.

No Candidate need attend unless requested to do so by letter from me.

Residence within the district required.  
 HENRY CHAS. TRENCHARD, Clerk to the Guardians.  
 Dated this 13th day of July, 1871.

PUBLIC SCHOOL EDUCATION IN IRELAND.

COLLEGE OF ST. COLUMBA, RATHFARNHAM, COUNTY DUBLIN.

VISITOR—THE LORD PRIMATE.

The College is intended for the Education of Boys from the age of nine years and upwards. The Course of Instruction is of the same nature as that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics, English, French, German, Drawing, and Vocal Music.

Boys are prepared for the Universities of Dublin, Oxford, and Cambridge, or for the Military and Civil Service.

Terms for Boarders—Sixty Guineas. A limited number of Sons of Clergymen can be received at Forty Guineas.

There are two Exhibitions attached to the School, tenable at the University of Dublin, value not less than £20 a year.

Lists of the School, and of recent honours gained by former pupils, together with all other particulars, may be had on application to the Rev. ROBERT RICE, M.A., of Christ Church, Oxford, Warden; or at Messrs. HODGER, FOSTER, & Co.’s, Publishers to the University, 104 Grafton street, Dublin.

The Summer Vacation ends on August 16.

**INFIRMARY FOR EPILEPSY AND PARALYSIS,**  
CHARLES STREET, PORTMAN SQUARE, W.

A VACANCY having occurred in the Medical Staff of the Infirmary through the resignation of Dr. John Harley, Candidates for the PHYSICIANSHIP are requested to send in their applications on or before Monday, July 31st. They must be Members or Fellows of the Royal College of Physicians of London.

By Order of the Committee,

July 1, 1871.

EDWARD WATHERSTON, Hon. Sec.

**FOR Varicose Veins and Weakness**  
**SURGICAL ELASTIC STOCKINGS**  
and KNEE-CAPS, pervious, light in texture, and INEXPENSIVE, yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise, a strong low-priced article for Hospitals and the Working Classes.

ABDOMINAL SUPPORTING BELTS, those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with EXTREME LIGHTNESS—a point hitherto little attended to.

Instructions for measurement and prices on application, and the articles sent by post from the Manufacturers,

Prompt attention to Country Orders. Terms, cash on receipt of goods, and no charge for package. Goods delivered free within 7 miles P.O. to be made payable to I. ISAACS and Co., at the Post-office, Tottenham court road.—Bankers, London and Westminster Bank

Established nearly hundred years.

**ESTABLISHED 1848.**  
**PROFESSIONAL AGENCY AND MEDICAL-TRANSFER OFFICE**  
50 Lincoln's-inn fields, W.C.

**J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c.,** (KING'S COLL.), and Author of **VIA MEDICA**, has always upon his books a large number of desirable investments and available Appointments for negotiation. Gentlemen wishing to relinquish practice can be introduced without delay to suitable successors with means at their disposal.

Dr. Langley devotes his prompt personal attention to the negotiations entrusted to him, which are treated with the most scrupulous reserve.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

Dr. Langley can refer to many of the leading Members of the learned Professions in town and country as a guarantee of his integrity and honour in all matters of business entrusted to him.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2.

**LOCUM TENENS.**—Dr. Langley has now organised a thoroughly reliable Staff of Suitable Gentlemen to take full Charge of any Practice which may require it in the absence of the principal, at fees from £2 2s. upwards, according to age, experience, qualifications, &c. One of these Gentlemen can be despatched by an early train after receipt of telegram or letter stating duties and terms. Office fee 10s. 6d. payable by the principal.

**PRACTICES AND PARTNERSHIPS NOW OPEN**  
for negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on receipt of two stamps) as below:—

Y 243. In a large COUNTY TOWN, within easy access of London.

Established 40 years, and owing to peculiar circumstances more than usually transferable. The receipts for many years past have been upwards of £800 a year. The returns during the last six months have been at the rate of £700 a year, exclusive of appointments, which realise about £50 a year. The vendor retires upon the advice of a London physician, to whom reference can be made. Visiting fees are 2s. 6d. and 3s. 6d. without medicine, in addition to mileage. A qualified assistant, who has been for many years engaged in the practice but prohibited from acting on his own account, can be retained if desired. The house is large and commodious, with large garden and detached stabling. The whole with a rental of £255. There is a local hospital, and the population of the town and district is upwards of 30,000. Excellent field sports in the vicinity. The parish appointment will shortly be vacant, and could be claimed by the successor.

Y 242. LONDON, West Central District. Receipts nearly £500 a year, capable of almost unlimited increase. The practice is wholly private, except appointments connected with the theatres. Rent £75 a year. The successor need not be married, and the practice can be conducted without assistant or carriage. An efficient introduction can be given.

Y 241. In a COUNTY TOWN, the centre of fashionable hunting district, an excellent Nucleus especially suited for a married gentleman who would receive resident patients. The private practice has been about £200 a year, but it has not been actively pushed. Appointments yield £50. The house is semi-detached, large, and with every convenience for the reception of epileptics, &c. There is also a garden, coach-house, stabling, &c. The whole supplied with gas, water, &c. An income of £600 a year may be derived from residents if the successor has a connection. Premium £150. Satisfactory reasons for leaving.

Y 240. In a pleasant London suburb, surrounded by a rapidly improving district of villa residences, a small but increasing FAMILY PRACTICE for TRANSFER. In consequence of the delicate health of the vendor the practice has not been actively pushed, and the receipts have amounted to about £400 a year; appointments, £50; no low midwifery. The practice can be conducted without a horse or carriage. Patients of a good class. The house is conveniently situate; rent £60 a year. The fullest investigation courted.

Y 239. LONDON.—The friends of a Medical Practitioner who is in a dangerous state of health, desire to secure a suitable successor. The receipts were formerly £2,500 a year, but have declined. A connection realising £500 a year, at least, could be secured by a suitable man, having the introduction of the vendor or his representatives. The house is situate in a large thoroughfare, contains twelve rooms, surgery, garden, green-house, &c., rent £50 a year, on beneficial lease. There is a hospital appointment which it is believed can be transferred. The expenses of conducting the Practice are small. Very easy terms would be accepted from a doubly-qualified gentleman, who could pay part of the premium in cash.

Y 238.—PHYSICIAN'S PRACTICE, with a Two years' partnership introduction. The connection is situate in a first-class inland watering-place, and yields upwards of £1,000 a year. The vendor occupies a good sociable position, and could introduce his successor to the best society. The residence is in a capital situation, and is suitable for a leading medical practitioner of the locality. References given and required.

Y 237. PHYSICIAN'S PRACTICE, receipts last year £1,740. The patients are of a good class, and there are very few debts. The Practice is situate in a large inland town frequented by invalids, and is believed to be transferable by a suitable introduction. The residence is detached, large, and convenient, with garden, &c. To an active gentleman, with first class diplomas, the introduction affords unusual facilities.

MEDICAL ASSISTANTS.

**VIA MEDICA.**—Essential to every Principal, Assistant, and Student.—Post free, 3s. 2d.

Dr. Langley's Quarterly List of Selecting PRACTICES and PARTNERSHIPS for JULY is now ready. Post Free on application!

## Original Communications.

### ON BLOOD-STAINS.

By H. C. SORBY, F.R.S., &c., &c.

MUCH attention has lately been directed to the detection of blood by means of its characteristic spectra, and a considerable part of what I have written on the subject has been reprinted or described in Dr. Letheby's paper.\* This, however, merely refers to what I had been able to ascertain six years ago, at the commencement of the application of spectrum analysis along with the microscope, when the instrument itself was in a most unsatisfactory state. I have since succeeded in making it far more perfect, and so much improved the methods of experiment, that what was then almost impossible can now be done without any serious difficulty. It, therefore, appears to me desirable that the readers of the MEDICAL PRESS AND CIRCULAR should be made more fully acquainted with the present state of the subject, not only on account of its purely scientific interest, but also because of its practical importance.

Since the publication of my earlier papers, I have found that the double tartrate of potash and soda is a most convenient reagent to be used to prevent the precipitation of oxide of iron in solutions containing free ammonia, and that the double sulphate of the protoxide of iron and ammonia is a much better deoxidising reagent than the simple sulphate, because it does not so readily become oxidised by keeping in coarse powder; and, being more bulky, a somewhat larger quantity can be used, which is important, since it is generally requisite to employ a piece so small as to be almost invisible. I have also found that for some special purposes boric acid and dilute hydrochloric acid are very useful. As named in my former papers, the glass cells used to contain the solutions for

examination under the microscope are best made from barometer tubing. The most convenient size is half an inch long, with an internal diameter of about one-eighth of an inch, for then they can be easily filled, or emptied and washed out, and yet they can be inverted or kept horizontal without loss of liquid, when it is desirable to remove any deposit or to let it settle to the side. These cells should be fixed on a piece of plate glass with purified gutta percha, since that resists so well the action of the various reagents.

The dispersive power of the spectrum-microscope should be sufficient, but not too great. It is a very common error to suppose that a high dispersive power will show the spectra better. This is true enough in the case of other departments of spectrum analysis, but, as a general rule, the absorption-bands due to solutions of organic colouring matters are much more distinct with a lower. The proper amount of dispersion is that which is so great as to well divide the bands, and yet no greater than will show them as dark as possible. If a considerably greater power be used the bands are indeed more widely separated, but are themselves so spread out and diluted that they become comparatively indistinct. On this account a solution which would show a well-defined dark band with a low dispersion might readily enough show none at all with a greater, in the same manner that in some cases all the important general characters of an ordinary microscopical object might be lost by using too high a magnifying power. In the case of the simple microscope much depends on using a power suited for each class of object, and so also in the case of the spectrum-microscope the amount of dispersion should vary according to circumstances.

There are spectra which require a considerable power, but this does not apply to those of such organic colouring matters as blood. I have made many experiments in order to ascertain what is the amount of dispersion which will separate the bands sufficiently to allow us to measure their position with all needful accuracy, and at the same time show them distinctly, and I have contrived a new form of direct-vision prism, lately made for me by Mr. Browning, which, in my opinion, is in all respects satis-

\* MEDICAL PRESS AND CIRCULAR, New Series, XI., June 7th, 1871, p. 481; and *The Doctor*, I., July 1st, 1871, p. 139.

factory. It consists of two rectangular prisms of crown glass, combined with one rectangular of very dense flint, and another less dense, of such an angle as to give direct vision. The result is that we obtain a good medium dispersion, and the side of the prism next the eye being inclined at an angle of forty-five degrees, the position of the absorption-bands can be measured by means of the screw micrometer proposed by Mr. Browning,\* and since then somewhat modified at my suggestion.

It would be a very great error to suppose that the detection of blood-stains depends merely, or even mainly, on the recognition of the spectrum of unaltered blood. If the stain were quite recent, the very well-marked spectrum of oxidised hæmoglobin would indeed furnish very excellent evidence, but even then our confidence may be very greatly increased by observing the various other spectra that can be derived from this colouring matter by the use of appropriate reagents. In the case of stains which have been kept a few days in the impure atmosphere of large towns, and even in that of those kept a few weeks in the purest air of the country, this is absolutely necessary, since they no longer contain unaltered blood. It is, therefore, important to understand the changes that occur in keeping, since they not only require us to modify our method of experiment, but may also furnish important evidence.

A fresh blood-stain on a fabric which does not contain any substance that will act chemically on blood, is easily soluble in water, and gives rise to a solution of oxidised hæmoglobin. This, when examined, would of course show the well-known spectrum, with two very distinct absorption-bands in the yellower half of the green. In the recent discussion of the subject much has been said about this spectrum of blood being different from that of any other substance. That may be true enough—at all events I do not know any that gives exactly the same, but there are some which give bands so far similar as to show the importance of studying the effect of different reagents. I have always said that our confidence in detecting blood depends on the character of the *various spectra* seen in particular conditions, and not on any *one spectrum*, independent of other facts. As thus understood, we may safely say that the spectra of blood differ most completely in the general character and position of the absorption-bands from those of any other known substance. My meaning will be better understood by describing a few particular cases. The colouring-matter of the petals of the red variety of *Cineraria*, when dissolved in water, gives a spectrum with two very well marked absorption bands almost in the same place as those in the case of blood, only they are of more equal width. However, in adding ammonia the spectrum of the *Cineraria* is completely changed; whereas that of blood remains the same, and therefore there is no kind of difficulty in distinguishing them at a glance. Cochineal also gives two bands not unlike those of blood, and the addition of a little ammonia makes them deeper, as is also the case in blood that has been partly changed to methæmoglobin; but on adding excess of boric acid the bands of the cochineal are raised very much towards the blue end of the spectrum, while those of blood remain unaltered, and therefore in this state there is no chance of confounding these two colouring matters. I do not know any substance which gives the same spectrum as blood when the solution contains excess of ammonia, and likewise when it contains excess of boric acid. This however is by no means the most striking character of blood, for its behaviour with reducing reagents and with acids is still more unique. Thus, on adding to the natural solution of blood a very little ammonia and a small quantity of the double tartrate of potash and soda, no change is produced; but if a portion of the double sulphate of the protoxide of iron and ammonia about one-fortieth of an inch in diameter be then added, and the whole slightly stirred, so as to mix uniformly without much exposure to

the air, the original two dark bands gradually fade, and are replaced by a single fainter and broader band in an intermediate position. This change takes place naturally when a solution of blood is kept for a day or two in a narrow cell, especially if closed with a cover, so that after a while the spectrum becomes indistinct. After being thus changed, when the solution is well stirred with a stout platinum wire flattened at one end and turned up square like a small hoe, the original bands can be again seen. This change by deoxidisation and reoxidisation serves to distinguish blood from by far the greater number of coloured substances. We may after this readily obtain another series of remarkable reactions. On adding a slight excess of citric acid the bands gradually fade, and if enough blood be present a new faint band may be seen in the red, but on then adding excess of ammonia, though this band is removed, the original bands are not restored, or only to a very slight extent. This peculiarity alone serves to completely distinguish blood from the great majority of colouring matters, which do indeed very commonly give a different spectrum when acid, to what they do when alkaline, but after they have been thus changed by the acid, they are restored by the alkali to the former state. There are very few which are permanently decomposed by a weak acid, like hæmoglobin is into hæmatin. The addition of a small piece of the ferrous salt to this alkaline solution of hæmatin deoxidises it and develops the spectrum of deoxidised hæmatin. This is characterised by a most unusually dark and distinct absorption-band in the green, and a fainter nearer to the blue end. When well seen this is a most striking and unique spectrum. Since deoxidisation takes place somewhat slowly, especially in cold weather, it is well to rather more than fill the cell with liquid and cover it with a small piece of thin glass, to prevent exposure to the air, and then to keep it and repeatedly examine it, until the spectrum is well developed, which may be perhaps after a quarter of an hour or more. On stirring so as to expose to the air, the dark band of deoxidised hæmatin disappears, and very commonly the bands of oxidised hæmoglobin can be again seen; for it appears that the addition of citric acid, as described above, does not completely change the hæmoglobin into hæmatin. We have thus another and quite different repetition of the same unusual sort of change produced by the deoxidising action of the ferrous salt in an alkaline solution, and this fact, combined with the character and position of the absorption-band, is alone quite sufficient to distinguish blood from any substance that I have yet examined. It will thus be seen that blood possesses quite a number of very special peculiarities, each of which alone would serve to distinguish it from nearly all other coloured substances, and when we bear in mind that all these peculiarities may be observed by using no larger quantity than one-hundredth of a grain in one single cell, they constitute such a remarkable and unique whole, that when we also consider the exact position of the absorption-bands, as seen by comparing together, side by side, the various spectra produced by a suspected stain and by a fresh specimen of blood, it appears to me next to impossible that any other substance could give the same results. At all events I think we may most confidently say that they serve to completely distinguish it from all known colouring matters. The behaviour of ordinary dyes, paints, and fruits is almost as different as could possibly be imagined.

Where a blood-stain is kept in a very damp place, the hæmoglobin is gradually changed into hæmatin, or both are completely decomposed. This corresponds with what occurs when a dilute solution is exposed to the air. If, however, a stain be kept dry, it is gradually altered into a mixture of hæmatin, and what in my first paper I called *brown cruvorine*, but which was named *methemoglobin* by Hoppe-Seyler at so nearly the same time, that I do not know which was the first proposed. At all events, his name has been more generally employed, and, therefore, I think it best to adopt it. A

\* *Monthly Microscopical Journal*, III., 1870, p. 68.

good deal has been written about this substance, and as I contend, some very erroneous opinions have been maintained. It is quite certain that it is in some way closely related to hæmoglobin, but whether it is only a peculiar molecular modification, or, as I have argued,\* hæmoglobin combined with an extra amount of oxygen, may still be considered doubtful. My reason for thinking that it is, so to speak, peroxidised hæmoglobin is that it may be at once formed from hæmoglobin by the action of oxidising reagents, and can be at once restored to the original state by deoxidisation. When a blood-stain is kept dry, this compound is gradually formed, and after a while we have a mixture of it with hæmatin, and a brown substance not yet much studied. When such a stain is digested in a small quantity of water, the methæmoglobin dissolves along with perhaps a little hæmatin, but the greater part of this latter is left insoluble, mixed with the brown substance already named. On examining the spectrum of a sufficiently strong solution, the methæmoglobin shows a moderately well-marked absorption-band in the red, and two or three other bands in the green, the relative distinctness of which varies much according to the more or less feebly acid or alkaline state. Now, one of the most interesting facts connected with this substance is, that when to the neutral solution obtained from a moderately old stain, a little of the double tartrate, and then a very small quantity of the ferrous salt are added, the spectrum of oxidised hæmoglobin is produced. If left long with excess of the ferrous salt, this becomes deoxidised, but on stirring, the spectrum of the oxidised form remains permanently. Since the methæmoglobin resists decomposition for a very long time when kept dry, we may, in this manner, obtain the spectrum of fresh blood from very old stains. I have even succeeded in developing it from a stain more than forty years' old. On adding ammonia to a somewhat strong solution of methæmoglobin, the band in the red is at once completely removed, those in the green are made much more dark, and a special characteristic narrow band is developed in the orange, and when this is deoxidised, we obtain hæmoglobin, which can be oxidised by stirring, and then afterwards all the other spectra can be developed, as in the case of fresh blood. As will be seen, these various facts are very remarkable, and they are quite unlike what I have seen in cases of any other substance. The rate at which the colouring matter of a fresh stain is altered into methæmoglobin varies very much according to circumstances, so that, as already named, the impure air of a large town will produce as much change in a few days, as the more pure air of the country in a few weeks. The weak acid of perspiration may also rapidly cause this alteration in the case of stains on worn clothing. If a stain has been kept dry in a town, and yet this change had not occurred, or only to a very slight extent, we might conclude that it was of recent date; but, if it had been, we could not be sure that it was old, for special causes might have produced a rapid change. In examining a stain that had been kept some days in a town, or in a house where gas was burned, we must, therefore, be prepared to find that the portion easily soluble in water does not give the spectrum of fresh blood, but merely somewhat obscure bands in the same situation, and a faint one in the red; but, by proceeding as already described, the spectrum of oxidised hæmoglobin may be developed, and thus we should have additional, very remarkable evidence that the stain was due to blood. We must, however, bear in mind that probably some unaltered hæmoglobin would be present, so as to modify the spectrum, and that some hæmatin might have been dissolved, so that the band of deoxidised hæmatin might be seen when the solution was completely deoxidised.

After digesting a somewhat altered stain in water, a considerable part of the hæmatin would be left insoluble.

This may then be dissolved by means of dilute citric acid, or diluted ammonia, and the presence of the hæmatin established by observing the spectra, when acid, alkaline, and deoxidised. We must be guided in our choice of the solvent by the nature of the fabric on which the stain occurs. If it be coloured, an unstained portion should be digested in dilute citric acid, and also in dilute ammonia, in order to ascertain whether either of these would interfere with the final result. In some cases dilute ammonia dissolves out a considerable amount of the dye, whilst citric acid does not, and then, of course, that should be used. In other cases ammonia is the best solvent, as for example where much earthy matter is present. This insolubility of hæmatin in water might often prove important, since sufficient might be left to enable us to detect it without difficulty when the blood had been so far removed by washing, that nearly every one would think it impossible to recognise that blood had ever been present. If the stain were on cloth, which had been so sponged and wiped that no mark whatever was left, it would generally be quite easy to detect the dried-up blood solution left in the tissue. In such cases, considerably more of dilute ammonia or citric acid might be used, than would fill an experiment cell, and the solution might be concentrated by evaporation at a gentle heat. Fortunately, hæmatin resists decomposition for a very long time when kept dry. I have found no difficulty in recognising it in the case of a stain forty-four years old; but, in some such very old stains, there is a large relative amount of a brown substance, which does not give any decided spectrum, and is apparently a product of the further change of hæmatin, perhaps analogous to that which may be formed by the action of strong ozone. Such stains could, however, be seldom of more than scientific or historical interest.

In all that I have so far said, I have assumed the fabric on which the stain occurs does not contain any substance that would at once change it into hæmatin, or act as a mordant, so as to prevent the solution of blood colours, and I have also supposed that no material amount of any other soluble colouring matter is present. Cases, however, might occur where the detection of blood would be most materially interfered with by one or all of these circumstances, and then it would be requisite to adopt different and special methods, according to the particular circumstances of the case. I shall not attempt to explain these here, for they have lately been fully described by me in a paper published in the *Monthly Microscopical Journal*,\* in which I have shown how all the difficulties that I have been able to think of may be overcome, and how blood may be recognised in the water, or soap and water in which stained clothes had been washed. I will, therefore, conclude this somewhat popular account of the general principles involved in the spectrum method of testing, by a description of the best method of preparing some of the more interesting objects, either for temporary inspection or for more permanent references. The spectrum of deoxidised hæmatin is seen to the greatest advantage, by deoxidising a solution of fresh blood boiled for a short time with dilute ammonia. This gives rise to a very pure hæmatin, free from unaltered hæmoglobin, which is nearly always present when it is changed by the action of citric acid, and makes the bands of the deoxidised hæmatin less distinct, by causing a general shading of the intermediate green. It is also free from the brown substance already named, so that the colour of the deoxidised solution is a fine, clear, and almost pink red. Such a preparation may be kept some time in one of the glass cells, by fastening down the cover with gold size, but objects for permanent reference should be sealed up hermetically in glass tubes. Those which I employ are half an inch in diameter, and about three inches long, made flat at one end like the bottom of a bottle, and drawn out taper at the other to a capillary tube, about as wide inside as

\* *Quarterly Journal of Microscopical Science*, X., 1870, p. 400.

\* Vol. VI., 1871, Pp. 9-17.

the thickness of a small pin. These are filled with an air pump, by placing them at the bottom of a tube about ten inches long, containing the solution, pumping out the air, and letting in the liquid over and over again, until only sufficient air remains to allow of the expansion of the liquid in hot weather. We need not trouble ourselves that a solution of fresh blood cannot be kept unaltered, since it can so easily be procured, but it is useful to have one of the deoxidised modification ready for reference. In all cases, the blood should be allowed to coagulate, and the fibrine separated by dissolving out the colour in water. A tube can then be filled with a solution of such a strength as to just show the two bands well divided, and a small quantity of iron filings previously or afterwards introduced into the tube by the small opening. After sealing with the blow-pipe, and keeping for a few days the spectrum of deoxidised hæmoglobin will be seen to great advantage, and undergo no sensible change after a year or more. Acid hæmatin solution of sufficient strength to show the band in the red may be prepared by the use of citric acid, and when sealed up, keeps unaltered for some years. My best specimen of deoxidised hæmatin was prepared by the action of citric acid on fresh blood solution, leaving it for a while, and then adding excess of ammonia. On sealing it up in this state, the decomposition of the other constituents of blood gradually, but completely deoxidised the hæmatin in the course of a year or so, and the solution is now, after three years, perfectly clear and free from deposit, and of a fine pink-red colour, showing the spectrum to perfection, with the principal band so dark and distinct, that all who have seen it, are astonished that any one could have said that such a band is only a "slight dimness." However, since it may not be convenient to wait until the solution has thus become deoxidised by its own decomposition, it may be deoxidised by the addition of ferrous salt. Such preparations keep for a year or two, but in many cases a coloured deposit has been formed, and the solution has become paler, which may perhaps have been due to my not having properly separated the fibrine in the first instance.

In conclusion, I would say that I hope no one will suppose that such diagrams of spectra as can readily be given by means of woodcuts are fair reproductions of their actual appearance. This is more especially the case when they have been copied over and over again, until, like those recently given in this journal, they have become extremely unlike my original drawings, and still less like the beautiful objects themselves.

BY H. LETHEBY, M.B., M.A., &c.

(Continued.)

"In the first group, with its largest masses of population, and its highest degrees of hardness of the waters, we elicit a yearly mean mortality of 21.9 per thousand of the living. In the second group, in which Edinburgh and Leith take their place, in spite of what should have been the advantage of the smaller masses of the population, the diminished hardness of the waters connects itself with a mortality increased to 24.9 per thousand. Passing to the

third group, in which Dundee and Paisley are situated, with what should have been the yet greater advantage of the masses of the population having undergone a further reduction, we find, with the still decreasing hardness, a still increasing mortality, the amount now rising to 26.3 per thousand. And in the fourth and last group, in which Glasgow, Greenock, Aberdeen, and Perth find their position, again the yet further diminished average of the masses of population foregoes its advantage, and the lowest proportion of hardness is marked by the highest proportion of mortality, which stands now at a yearly average of 28.5 per thousand of the living. This result, by its near correspondence, confirms that arrived at by Dr. Letheby and his associates from their less ample details, which, with an average hardness of 14.9, give a mortality of 22.2, and with a hardness averaging 4.9, a mortality of 26.1; the mean of the last three groups, as detailed above, being, when taken together, 4.2 of hardness, and 26.6 of mortality. If this so uniform descending in the hardness of the water, and climbing of the rate of mortality, could be viewed as but a coincidence, it carries with it, at least, a terrible consistency that may well arrest attention. But to regard it as a mere coincidence, would be manifestly to reject unreasonably the best description of evidence which such a subject is capable of admitting. It is true that the condition of health of a community is contingent, not on any single natural influence, but on the mutual actions and reactions of a variety of agencies in relation to regimen, diet, atmosphere, &c., on the presence of which, in greater or less purity or cogency, the general issue depends. But it is the province of statistics, should the result, in any individual example, appear to be affected by the failure or predominance of any individual agency, to spread the inquiry over an enlarged field, so that the disturbing element in one direction becomes neutralised by the existence and adduction of a compensating element in another. And, above all, it is to be noted whether, however other elements may waver, there be one element that is uniformly present, and in a ratio that is ever capable of being nearly determined. Such an element, so capable of being known and measured, we have here, along with the water itself, in the varying quality of its hardness, as denoting the degree of its impregnation with carbonate of lime; beside which must be placed the other superior properties of a water with which that impregnation is customarily associated."

SUMMARY ABSTRACT OF TABLES.

| Degree of Hardness. | Number of Towns. | Average Death rate per 1,000 of Population. | Average Degree of Hardness. |
|---------------------|------------------|---|-----------------------------|
| Over 10 . . .       | 25               | 21.9  | 16.0                        |
| 10 to 6 . . .       | 17               | 24.9  | 8.0                         |
| 6 to 2 . . .        | 15               | 26.3  | 3.8                         |
| 2 and under .       | 8                | 28.5  | 1.3                         |

And, lest the true meaning of these tables should be misapprehended, it is right to say that they do not in any sense imply that soft water is the immediate cause of the higher rates of mortality, but that hard water is, in some way, concerned with the preservation of the public health. The results, in fact, show that in a number of large towns with every variety of hygiene, as regards situation, whether it be inland or near the sea-shore, at high elevations or at low, with every degree of overcrowding and every description of industrial occupation, there is concurrently with the use of soft water a high death-rate, and with that of hard water a low. It is remarkable, moreover, that, *pari passu*, with the downward degree of softness there is an upward movement of mortality. The inference from this is not that soft water kills the people, but that hard water protects them from the untoward influences of a city life; that it gives vigour to the constitu-

\* Read before the Association of Medical Officers of Health on Saturday, May 20.

tion, and enables it to resist the action of unwholesome agencies.

"Nor is it alone by the greater proportion of deaths that the action of an insalubrious influence is denoted. There are a thousand petty ailments and discomforts, which, with as subtle a force as that produced by a prolongation of east winds, renders existence uneasy without making it immediately unsafe. It is not mere life for a population that is to be desired, but a consciousness in it of tone and vigour, and of mental as well as bodily elasticity. There are those who, when they defend the qualities of a water that has been challenged, surprise us by seeming to speak as if it was to be expected that, when an unwholesome water is introduced in one year into a city, in the very next ensuing years we should see already rickety children crouching at the thresholds, and the streets thronged with men with sallow faces, craving for mental and physical stimulants to relieve life of its irksomeness, and to quicken it into feverish excitement while they hasten on its close." But Nature does not work in such fashion, for "when she tends towards perfection, it is by slow degrees; and we mark the completed stages of the progress, or its final result, rather than the progress itself. And it is not otherwise when the course imposed upon her is one of deterioration. Each generation bears with it a downward tendency, which it bequeaths to a succeeding generation, to be again intensified and again transmitted; more frequently adding, yet sometimes subtracting, a modicum till the measure is complete. It is by statistics that we strive to mark the stages; but in all statistics a main element is time."

"Upon the whole," therefore, says the physician, "I think that few who have followed this inquiry with attention, and will weigh what has been demonstrated for a hard and against a soft water, with an unchanging consistency throughout of direct as well as collateral evidence and argument in regard to both, will wonder that the Commissions at Paris, Vienna, and London have finally decided in favour of a hard water. Of the new waters designed for Paris, the copious sources of St. Philbert and of Armentières, to be brought from a distance of about eighty miles, have an average hardness of 12·46 per gallon, while of those chosen for Vienna, the still more copious source of the Kaiserbrunnen, of ancient fame, and forty miles from the city, and those of the Stixenstein and the Antonioquelle, show an average hardness per gallon of 8·82 degrees." The hardness of the water of the Thames which is supplied to London is about 15·5 degrees; and all these are recognised as excellent waters for the supply of large cities.

With this, says the physician, I conclude, and having seen in the course of the argument that, while on one side random assumptions have crumbled down into nothing, on the other, carefully gathered proofs and authorities have accumulated into solid strength. "Perhaps never, certainly rarely, has any kindred scientific demonstration, positive as well as negative, been more complete, in any reasonable sense of what is possible with our finite means of knowledge." And now, finally, I will recapitulate the conclusions which he holds to have been established.

1. The human body needs for its structure and maintenance the supply of certain salts, among which are the carbonate and phosphate of lime, these being in a special manner required to give stability to the bones, but having also their further uses in the living economy.

2. The phosphate of lime is supplied to us in our ordinary animal and vegetable food, but is not presented to us in water.

3. The carbonate of lime, on the contrary, is not primarily presented to us in sufficient quantity in our solid food, but is contained in variable and more fitting proportions in spring and river waters.

4. It is from the carbonate of lime brought down by rivers into the sea that all marine animals derive the denser parts of their construction, the remains of which, during the progress of geological periods, have been, and

continue to be, aggregated into huge expanses of limestone rock.

5. What has sufficed for the wants of these lower animals has sufficed also for those of the higher organisations of which man is the head.

6. Positively, this is proved and confirmed by the fact that it is in the limestone districts, where the waters are more or less hard, that man has been shown to have reached his most vigorous average physical development.

7. Negatively, this is proved also by its having been found that the mortality of our principal towns increases, on a calculation of averages, in the proportion that the hardness of the waters is diminished.

8. A water containing about six grains of carbonate of lime is nowhere held to be a hard water, but is fitted for every use of domestic economy or manufacture.

9. Such a water, whether as a drink, or as combined with our food, presents to us in the most regular and constant of forms, and in its most simple, natural, and easily appropriated state, the carbonate of lime required for the healthy maintenance of the living system; while it is otherwise naturally preferable, because imbued with more agreeable qualities, and with higher refreshing and invigorating powers.

10. A lake water, independent of the consideration of its low impregnation with carbonate of lime, is further objectionable from its deficiency of air and carbonic acid, its extreme coldness in winter and tepidness in summer, its combination with peaty and other matters, the abundant presence of living animal and vegetable organisms, and its general want of sapidity and agreeableness, and, consequently, its lower refreshing powers.

11. These views, so obviously concordant in fact and reason, are consistent with the natural tastes and instincts of all peoples in all ages, have been maintained by the mass of scientific men in all countries, and have been publicly ratified through the results of repeated Government inquiries.

12. Therefore, wherever a community has a choice between a water immediately derived from springs, and thus moderately impregnated with carbonate of lime, the excellence of which no one questions, and a lake water, the defective qualities of which are denounced by many, it ought unquestionably to prefer the former, on every probable consideration of comfort, health, convenience, and, in the end, were it on no other grounds than these, of the truest economy.

## CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE VI.

*Menorrhagia continued—Granular ulceration of cervix uteri—Treatment of—Granular condition of cavity—Treatment of—Mode of dilating cervix—Sponge tents—Sea-tangle bougies—Barnes' Dilators—Nitric acid use of—Curette—Placenta retained after abortion.*

In my last lecture I dwelt at some length on the subject of subinvolution of the uterus, as bearing on that of menorrhagia which is nearly always associated with it, and I mentioned that that unhealthy condition of the uterus predisposed to the occurrence of ulceration of the cervix, but this affection is often met with independent of subinvolution and is by itself capable of giving origin to profuse menstruation.

Mere abrasion of the lips of the os uteri is not sufficient to produce menorrhagia, but that unhealthy spongy condition of the cervix in which the mucous membrane lining its canal becoming hypertrophied and thickened, bleeds on the slightest touch, the os being patulous and the lips everted, is quite capable of originating severe menorrhagia. A young married woman, aged twenty-four, who had never been pregnant stated that she had become greatly debilitated by the excessive loss which occurred at each menstrual period. She had been treated by ergot and astringents exhibited by the mouth, and by injections of alum and water, but this treatment produced no good effect. A vaginal examination proved the existence of extensive granular ulceration of the os and cervix uteri. Now in severe cases such as the one I am referring to, you may rest satisfied that the unhealthy condition of the mucous membrane extends at least as high as the os internum, and that you will fail to effect a cure unless your treatment reach every portion of the diseased tissue, therefore with the view of permitting the necessary applications to be made to the whole extent of the cervical canal, I commenced my treatment by introducing two tents of compressed sea tangle, two pieces being sufficient for the object I had in view, which was not to open the uterus to such an extent as to enable me to examine its cavity, but only to permit me to treat the entire of the cervical canal. I left these pieces *in situ* for twenty-four hours, and on withdrawing them after the lapse of that time I cauterised freely the whole of the diseased surface with strong nitric acid. This did not cause any pain. On examining the os uteri a few days subsequently I found it in a much healthier condition, the menorrhagia never returned, and although a considerable time elapsed before the uterus regained a perfectly healthy state, still the progress of the case was rapid and the cure perfect, the only treatment subsequently necessary being the occasional application of a twenty grain solution of nitrate of silver to the os uteri, and at a later period of small blisters over the sacrum; finally not the slightest trace of the ulceration remained and menstruation became in all respects normal. The foregoing case illustrates perfectly the mode of treatment I as a rule adopt. Of course it is not always necessary to dilate the cervix uteri. If the case be recent and you can satisfy yourself that the unhealthy condition of the mucous membrane does not extend very high, the use of the solid nitrate of silver or brushing the part lightly over with nitric acid may be sufficient; but in the more severe forms of the disease such treatment will prove to be merely palliative, and the only effectual one will be found to consist in that which I have advocated. I believe not a little of the opprobrium which rests on obstetric practitioners for the length of time over which their treatment extends, is due to excessive timidity and to the use of inefficient remedies.

A condition very analogous to that which we can see in the cervical canal, occurs also in the interior of the womb as the result of congestion and inflammation of the lining membrane of that cavity, a fact which is often overlooked; indeed the majority of systematic writers altogether omit mention of it. Dr. Tanner in his excellent work on the "Practice of Medicine" mentions the "existence of an unhealthy pulpy condition of the mucous coat" of the uterus as a cause of menorrhagia. My own experience leads me to conclude that while a "pulpy" condition is rare, chronic disease producing a rough granular state of the mucous membrane lining of the cavity of the uterus and giving origin to menorrhagia is far from being uncommon. This condition I believe to be in many respects analogous to that so commonly met with in the eyelid, and you will fail to cure the menorrhagia which it causes till you have destroyed the granulations on the mucous membrane and restored it to a healthy state, just as you would fail to relieve the ophthalmia depending on granular lids till you have cured the palpebral affection. I may here take the op-

portunity of laying down a rule on which I always act, and one which I advise you to adopt—namely, that when ever you meet with a case of menorrhagia in an otherwise unhealthy woman which a careful vaginal examination proves not to depend on ulceration of the os and cervix uteri, on an extra-uterine polypus, on cancer or such evident cause, to dilate the cervix and os internum with the view of determining what the condition of the interior of the womb may be. This I hold to be your manifest duty.

I cannot refrain from quoting the judicious remarks of Dr. Tanner with reference to this subject. He says speaking of menorrhagia—vol. ii., p. 301—"When a woman suffers from repeated attacks of uterine hæmorrhage which can only be partially or temporarily relieved by rest, nourishing food and proper astringents, we may be sure that there is some organic disease of the ovaries or uterus; and though the cervix and body feel healthy to the touch, we can be certain that the bleeding is due to some actual disease, that it is not functional." And further on after enumerating what these causes may be he adds, "There is only one plan of treatment which can be adopted with a reasonable hope of success, and that is to dilate the os and cervix thoroughly so as to permit the removal of the source of evil." I fully endorse these observations. There are two methods still practised of accomplishing this object, the one with sponge tents, the other by means of sea tangle. The former can be made of any required size, it is merely necessary to cut a fine clean sponge into pieces conical in shape and of various size and lengths, for you should always be provided with several tents of different sizes before commencing the process of dilatation. You should then wrap each piece as tightly as possible with fine twine commencing at the narrow extremity and winding it on till it reach the thick end. The pieces of sponge should then be immersed in a strong solution of gum arabic, left in it till thoroughly saturated, and then hung up to dry slowly. Before these are used the surface should after the removal of the twine be rubbed smooth. A small sized tent is to be first inserted, a larger one being introduced on its removal after the lapse of from six to twelve hours. I have entirely given up the use of sponge tents myself: they are troublesome to prepare, give rise to a very foetid discharge, and are further objectionable because the mucous membrane lining the cervix sinks into the cells of the sponge which is consequently lacerated as the tent is withdrawn, and thereby the risk of inflammation occurring is greatly increased; besides sponge tents from their conical shape necessarily dilate the os externum far beyond what is required before the os internum is opened even to a moderate extent. In fine sponge tents should never be used if sea tangle can be obtained. Tents made of this substance, technically called *laminaria digitata* have been in use for some years for the purpose of dilating the cervix. The method first adopted was to introduce one which after the lapse of some hours was withdrawn and another of greater calibre introduced in its place, the process being repeated till the os internum was sufficiently dilated. This process was necessarily very tedious and besides objectionable in other points of view. It is now given up and a modification of it introduced by Dr. Kidd of this city adopted in its place. Dr. Kidd's method possesses these three great advantages—that it is comparatively rapid, that it is cleanly, and lastly and most important of all that it dilates the canal equally throughout its whole length, except in some cases of rigidity of the os internum to which I shall allude presently.

Having decided to dilate the cervix the first step is to expose the os uteri by means of the duck-bill speculum, next to seize the anterior lip with a small hook and with it to draw down and steady the uterus as shown in Plate II. You should previously measure the depth of the uterus and have ready several pieces of sea tangle bougies, each piece being at least the length of the uterine

Plate II. You should previously measure the depth  
 of the uterus and have ready several pieces of sea tangle  
 bougies, each piece being at least the length of the uterine

cavity. These you now proceed to introduce, the main difficulty is nearly always with the first, and this difficulty is greatly increased if the uterus be retroflected. The short lengths not being so easily manipulated as longer ones I sometimes when difficulty occurs take an entire bougie and pass it through the os internum as I would the sound. I then slip pieces of the proper length in beside it, for when we have inserted one piece it straightens the uterus and serves as a guide to the others. When several pieces have been introduced you can withdraw the long one, or if before passing it you nick it round at a point corresponding with the length of the other pieces you may be able to break it there, and so avoid the trouble of having to substitute another length in its place. The number of pieces you should insert varies in each case. If the patient have never been pregnant and the cervix rigid you will not be able to get in more than three or four, but if she have borne children or if the cervix be relaxed you may succeed in introducing double that number, or even more without difficulty.

If a small number only have been introduced, it is better to withdraw them after the lapse of nine or ten hours and introduce a larger number; but if seven or eight pieces have been inserted they may be left for twenty-four hours before any further steps be taken. The sea tangle rapidly absorbs moisture from the vagina and uterus, and swells, and by swelling forcibly dilates the cervix. This of course causes pain which however is seldom very severe and generally passes off after a few hours. If it continue I usually direct a morphia suppository to be introduced into the rectum, or 20 grains of the hydrate of chloral to be administered at bed time. Dr. Graily Hewitt who still advocates the use of the sponge tents in preference to the sea tangle, states, as an objection to the latter that it is liable to slip out. This certainly is true if you use the short tents which are sold in boxes, but if you use pieces of the bougie of the length already specified and take care that they pass up to the fundus, there is very little chance of them being expelled; on the contrary I have on two or three occasions experienced some difficulty in removing them. This has been the case when the os internum was so rigid, that it prevented the sea tangle expanding as freely at that point as it did in the cavity of the uterus and in the cervical canal; and the pieces of tangle being thus constricted in the middle, it was necessary to press the index finger of the left hand firmly against the lip of the os uteri, while with a pair of long forceps held in the right hand one piece is seized and slowly extracted. These are the cases in which as just mentioned the whole extent of the canal is not equally dilated, and then fresh pieces of the tangle must be introduced and time given to allow of them to expand, before proceeding to explore the interior of the uterus. You will however from time to time meet with cases in which although the sea tangle has expanded to its fullest extent, still from the size of the tumour or some other cause the os internum is not as large as you would desire. Under such circumstances I usually complete the process by the introduction of one of Dr. Barnes's dilators. These are Indian-rubber bags of a somewhat hour-glass or rather fiddle shape. They are made of three different sizes. One end terminates in a long slender tube, the extremity of which is furnished with a stop-cock. The dilator is introduced in a flaccid state into the uterus on the point of a staff or sound, the terminal bulging part being carried through the os internum, and air or water being then gradually forced into the dilator through the long tube just alluded to, it is left for an hour or two, and by that time has generally distended the canal to a considerable extent. The peculiar shape of the dilator prevents it when once it has been distended, from slipping out of the uterus. Dr. Barnes originally introduced these bags into practice for the purpose of dilating the os uteri in cases in which it was desirable to induce premature labour, a purpose which they often serve admirably, but their use is now further extended, and we use them occasionally for

the purpose of completing the dilatation of the cervix in the unimpregnated uterus.

You have had frequent opportunities of seeing the process I have described carried out—and must have noticed the entire absence of unpleasant symptoms, after a proceeding so apparently severe as the forcible dilatation of the cervix uteri—I have therefore no hesitation in recommending you to adopt this course in your future practice, as being one which you have seen productive of such good results in this hospital.

I have now explained to you the mode by which dilatation of the cervix is to be accomplished. It remains for me to direct your attention to the way in which you are to proceed, when having withdrawn your sea tangle or sponge tents, you desire to clear up the doubt which exists and satisfy yourself as to the cause of the menorrhagia. Attempts have been made to examine the interior of the uterus by means of the endoscope; but as yet with negative results, the hæmorrhage which in these cases is always present to at least some extent, and the mucous discharge which is continually being poured out prevent any thing being distinctly seen. We are therefore obliged to rely on the sense of touch alone, and must therefore pass the index finger fairly through the os internum till the tip reaches the very fundus. To accomplish this by no means easy matter, it is necessary in the first instance to draw down and fix the womb, this you effect by seizing the anterior lip of the os uteri with a vulsellum, which you intrust to an assistant to hold, while the fundus should be at the same time pressed down by your left hand or better still by another assistant, the finger well oiled is now introduced slowly through the os internum, and swept round the entire cavity of the uterus. You will thus detect the existence of a polypus or a tumour no matter how small, should either be present, while the educated finger will recognise the rough uneven feel which the mucous membrane if in an unhealthy granular condition conveys to the touch.

I have already expressed my opinion that this condition of the living membrane of the uterus is probably due to subacute inflammation, this view I believe to be correct, but be the cause what it may, the mode of treatment should be the same, and that is to destroy these so-called granulations "and endeavour to excite healthy action in the diseased part." With this view I invariably make use of the strong nitric acid, applying it with extreme freedom to the interior of the uterus. In the present case it is necessary to reach the entire of the diseased surface, for if the acid be applied imperfectly or partially the irksome process of dilating the cervix must be gone through again, I apply the acid by means of a thin strip of lint wrapped firmly round a piece of stick, or better still fastened through a loop of iron wire, such as that at the end of the stilette of an ordinary catheter, the os is brought into view by the use of the duck-bill speculum which protects the posterior wall from any task of injury, its concavity being smeared with lard to prevent the acid from corroding it, while the anterior wall is guarded by the vulsellum with which the lip is still firmly held, the stick or wire armed with the piece of lint saturated with the acid is passed boldly and rapidly through the dilated cervix, swept round the entire of the interior of the womb and with drawn, another piece of lint soaked in water should be at once applied to the os to prevent the vagina being injured by any acid discharge which might issue from the uterus, and then the lip being freed from the grasp of the vulsellum and the speculum withdrawn, the patient is to be placed in bed.

The subsequent treatment is very simple, should the patient suffer pain which she seldom does to any great degree, I order a morphia suppository to be introduced into the rectum, but even this in many cases is unnecessary, indeed much less pain is caused by this application than by the introduction of the solid nitrate of silver, though this latter would seem the milder treatment of

the two; this immunity from pain after the acid is I think, partly at least due to the circumstance that the cervix and the os internum have been previously dilated. At the end of five or six weeks I introduce the speculum and examine the condition of the os. The slough caused by the nitric acid has generally by that time separated and you have a healthy granulating surface exposed to view. I brush this over with a ten grain solution of nitrate of silver at intervals of a day or two, and in a fortnight, as a rule it is perfectly healed. You can doubtless recal to mind several of the cases which have been treated by this method during the past session, the following one which is at present in the house, serves as an example:—J—C—, a married woman, at twenty-eight, admitted 26 Nov., 1870, has never been pregnant. Menstruation regular till within the last few months when she observed the flow to become much more profuse than formerly and to last for a greater number of days. Latterly the interval between each period has been but a fortnight. She has suffered and continues to suffer greatly from severe pain over the left ovary and in the back. On making an examination per vaginam the os was found to be relaxed and patulous, the sound penetrated to the depth of nearly three inches, the fundus appeared to be slightly enlarged. The existence of a small polypus or fibrous tumour being deemed possible dilatation of the cervix was decided on, five lengths of compressed sea-tangle were introduced on the morning of the 3rd Dec., on removing them next morning the os internum was found still too contracted to admit of the passage of the finger, Barnes's small sized dilator was consequently introduced and maintained in the cervix for a couple of hours. On removal I was able to introduce the finger and to reach the fundus, but neither polypus nor tumour could be detected in the uterus, the inner surface however was felt to be rough and uneven, the entire of this surface was freely cauterised with the strong nitric acid; this patient was discharged on the 21st Dec. perfectly well. Such is the treatment I nearly invariably adopt, of course circumstances occasionally require me to modify it somewhat. Were the patient in a very feeble debilitated condition I should endeavour in the first instance to improve her health, restraining the menorrhagia by plugging, by alum injections, or by hot water-bags applied to the spine; but this treatment would be altogether palliative, and I should as soon as possible have recourse to the radical plan I have just advocated.

Two other modes of treatment have been practised to which it is right I should call your attention, namely, the injecting into the uterus of astringent or caustic fluids, and the scraping of the inner surface of the uterus with an instrument called the curette. I do not think either of these modes of treatment as safe or as satisfactory as that just detailed. Inflammation of a serious and even fatal character has followed the injection of fluids into the cavity of the uterus, and I look on it as a hazardous practice. If any of you gentlemen should be induced to try it hereafter, let me recommend you in the first instance to dilate the cervix so that the injected fluid may have a ready means of exit. As to the curette, it is in my opinion a most unscientific instrument, and ill adapted to attain the object in view. This instrument is intended to detach any soft bodies which may exist in the interior of the womb; in plain English the object is to scrape its lining membrane, and as this has to be done almost at random, it is evidently a mere chance whether it effects the object in view or not. Récamier himself who invented it advocates the cauterising of the interior of the uterus with nitrate of silver after the curette has been withdrawn,—a clear proof that the use of the instrument even in his own hands proved to be inefficient. There is just one case in which in my opinion the use of the curette is justifiable, that is for the removal of a small polypus the size of a pea or bean, and which it is difficult to seize with a forceps for the purpose of twisting off, and yet may be too large to be easily destroyed with nitric acid. But then the cervix should have been previously dilated, and

the instrument be guided along the finger to the required point.

The retention of a portion of the placenta or of the foetal membranes is so well known a cause of uterine hæmorrhage that it needs but brief notice. Not long since we had in hospital a case to which I feel it is right I should call your attention. This woman was the mother of five children. Early in February she had a miscarriage at about the fifth month of pregnancy. There was considerable hæmorrhage at the time; the discharge did not entirely disappear for four or five weeks. After an interval of about a fortnight a red discharge which she supposed to be the regular menstrual flow appeared, and continued with short intervals till the 1st May, when she came under my care. On examining her I found the uterus to be much enlarged, the sound penetrating to the depth of four inches. The large size of the uterus and the freedom with which the sound rotated in the cavity induced me to suppose that it contained a tumour of some kind, and I determined to explore the interior. I accordingly dilated the cervix, and on passing my finger through the os internum detected what appeared to be a polypus attached by a slender pedicle to the uterine wall. I seized it with a vulsellum and using very slight traction extracted it, when I found it to be a portion of placenta which had been retained in utero for nearly three months, giving rise to the symptoms I have detailed.

From what I have told you as to the causes on which menorrhagia depends, you will understand why it is that astringents and hæmostatics administered by the mouth, are so frequently ineffectual in stopping the hæmorrhage. You are not however to suppose that they are useless. On the contrary, they are frequently productive of much benefit and generally are valuable adjuncts to our surgical treatment. In cases of profuse menstruation depending on subinvolution, you will often find ergot to check temporarily the discharge. I generally give the liquor ergotæ in twenty drop dose every four hours. If the patient be anæmic, I usually administer along with it ten drops of the tincture of the perchloride of iron. Recently I have been trying the effect of strychnia in combination with ergot and am satisfied that it greatly increases the peculiar action of the former drug on the uterus. I have not tried it as yet in labour, but you have had an example of its effects in the case of the patient, who was admitted for profuse hæmorrhage coming on three weeks after abortion at the fourth month, which I believe to have been kept up by the retention of the placenta. You may have remarked that each dose of the ergot and strychnine was followed by sharp uterine pains, which resulted in the expulsion of the placenta. I recommend you to try in your future practice this combination. Gallic acid too, alone or in combination with ergot, is an admirable medicine, and often produces excellent effects. I usually give both in ten grain doses. The mineral acid and acetate of lead are extensively prescribed in cases of menorrhagia. They are however, very unreliable agents.

[We regret that by a printer's error the woodcut of modified *écraseur* was inserted in our last issue in place that of the intra-uterine *porte-caustique* referred to by Dr. Atthill in his lecture.—ED. M. P. AND C.]

#### STATISTICS OF VENEREAL DISEASE IN THE 2ND BATTALION 7TH ROYAL FUSILIERS.

By D. MACKIE, M.A., M.D., Assist.-Surgeon.

At the present time, when the statistics of venereal disease are eagerly studied and canvassed both by the advocates and by the opponents of the Contagious Diseases Acts, it may not be without interest to examine the vicissitudes in the amount of venereal which a single corps has

experienced during the last nine years. In the case of the above-named battalion this interest will not be diminished by the circumstance that during that period it has been stationed in Gibraltar, Malta, Canada, and England successively; thus affording us the means of judging of the effect on the amount of disease, produced by the different circumstances in which the soldier is placed in these widely separated stations. Another advantage for this examination which this corps presents is, that during the whole period of nine years no change in the means of prevention has been made in the regiment, so that the variations in the amount of disease are entirely due to extraneous causes.

From Gibraltar, where the Royal Fusiliers were stationed for several years, we went to Malta in the autumn of 1863; we left Malta for Canada in the spring of 1865; and we returned from Canada to England in the summer of 1867. At Gibraltar and Malta strict sanitary supervision of the women obtains. In Canada, although there exists on the Colonial statute book a Contagious Diseases Act, formed on the Imperial model and for the benefit of the Imperial troops, it was not put in force at the stations where we were quartered, nor as far as I am aware at any other station in Canada.

With these preliminary remarks, I give in the following table the annual amount of venereal disease in the battalion at the different stations mentioned; premising that in this as in the rest of the tables this amount is calculated as the rate of admission into hospital per annum per 1,000 of mean strength.

Table No. 1. Royal Fusiliers.

| Gibraltar. |      |      | Malta. |      |      | Canada. |      |      | England. |      |      |
|------------|------|------|--------|------|------|---------|------|------|----------|------|------|
| 1861       | 1862 | 1863 | 1863   | 1864 | 1865 | 1865    | 1866 | 1867 | 1867     | 1868 | 1869 |
| 183        | 151  | 144  | 71     | 31   | 25   | 65      | 68   | 102  | 398      | 273  | 310  |

The difference in the amount of disease suffered by this corps in these four stations is thus very manifest; Malta showing the least amount, Canada and Gibraltar occupying the second and third places respectively, and England standing at the top of the scale. This relation will be more obvious if we take the average of the three years at each station. These averages give us the following comparison:—

| Malta. | Canada. | Gibraltar. | England. |
|--------|---------|------------|----------|
| 48     | 78      | 159        | 327      |

We thus find that the amount of venereal in the Royal Fusiliers at the above stations was very nearly in the geometrical progression 1, 2, 4, 8; in other words, whilst it was nearly twice as much in Canada as at Malta, at Gibraltar it was quite twice as much as in Canada, and in England it was more than twice as much as at Gibraltar.\*

The small proportion of venereal among the troops at Malta is generally attributed to the stringent enforcement of compulsory treatment of the diseased women. That the strict police supervision to which the women in Malta are subjected has really very much to do with this small proportion of disease among the troops seems to me almost proved by the following table, compiled from the official returns, and giving the amount of venereal in the garrison during a period of ten years:—

Table No. 2. Malta Garrison.

|      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|
| 1859 | 1860 | 1861 | 1862 | 1863 | 1864 | 1865 | 1866 | 1867 | 1868 |
| 149  | 148  | 102  | 59   | 44   | 53   | 44   | 60   | 54   | 70   |

By a glance at this table we see that in the last seven years the amount of disease was more than one-half less than in the first three, the exact average of the last seven years to that of the first three being 53.5 to 133. The reduction evidently began in 1861, but was not fully accomplished until the following year; and it is officially

\* Calculating from the official returns of venereal among all the troops quartered at those four stations during the same years, we find that instead of the progression 1, 2, 4, 8, which obtained in the Fusiliers, the ratio was nearly 1, 3, 4, 6.

“attributed to the adoption, in the middle of 1861, and to the efficient execution, of a system of police surveillance of the prostitutes.”\* In order fully to appreciate the extent of the diminution it is necessary to omit the intermediate year 1861, in the middle of which the system of police surveillance is said to have been established, and to compare the two years preceding its adoption with the seven succeeding. The average of the two former years we see to be 148.5, that of the latter being, as already mentioned, 53.5; in other words, the effect of the new system was to reduce venereal among the troops to nearly one-third of its previous amount. If, then, it be true that “a system of police surveillance of the prostitutes” was first strictly carried out from the middle of 1861, it seems impossible to avoid the conclusion that the decrease of disease in the garrison was owing to this circumstance; but opinions will probably differ as to the mode in which this cause effected the diminution.

At Gibraltar, where the women are subject to a similar police supervision, we have seen that the Royal Fusiliers had nearly four times as much disease as at Malta. To institute a comparison, however, between Gibraltar and Malta, it is desirable to have statistics on a larger scale than that furnished by a single corps, and during a longer period than three years. I have therefore compiled the following table from the official returns in order to show the amount of venereal in the whole garrison at Gibraltar during the same period of ten years over which Table No. 2 extends.

Table No. 3. Gibraltar Garrison.

|      |      |      |      |      |      |      |      |      |      |          |
|------|------|------|------|------|------|------|------|------|------|----------|
| 1859 | 1860 | 1861 | 1862 | 1863 | 1864 | 1865 | 1866 | 1867 | 1868 | Average. |
| 259  | 172  | 233  | 134  | 127  | 158  | 149  | 156  | 214  | 225  | 188      |

Throughout the whole of this period police surveillance of the women was maintained at Gibraltar; and though the above table shows great oscillations in the amount of disease, there was no great permanent change as at Malta. The question, however, remains—how is it that there should be so much more venereal at Gibraltar than at Malta? From the table we find that the average amount at Gibraltar is 188; that is 3½ times the average amount at Malta since the adoption in 1861 of police surveillance there; while even before 1861 the rate at Malta was less than that at Gibraltar in the proportion of 148.5 to 188. From this comparison we may conclude that the police surveillance of women is but one factor out of several in determining the amount of venereal among our troops. It seems indeed far from impossible that in other places, amid other circumstances and other ways of life, the police supervision of the women might have an entirely opposite effect to that which it has been shown to have had at Malta. In Canada, where no such police surveillance is exercised, we have seen that in the Royal Fusiliers the amount of disease was only one-half what it was at Gibraltar. The amount in this corps, however, while in Canada, was exceptionally small in proportion to the average rate of venereal diseases among the whole of the troops on that station, as will be seen from the following table, which gives the same information regarding the troops in Canada as the last two tables give with respect to those at Malta and Gibraltar:—

Table No. 4. Canada Garrison.

|      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|
| 1859 | 1860 | 1861 | 1862 | 1863 | 1864 | 1865 | 1866 | 1867 | 1868 |
| 102  | 113  | 129  | 145  | 191  | 206  | 159  | 139  | 183  | 193  |

This table gives 156 as the average amount of venereal among the troops in Canada; so that the average rate of disease in the garrisons of the three foreign stations stands as follows:—

| Malta.       | Malta.      | Canada. | Gibraltar. |
|--------------|-------------|---------|------------|
| Before 1861. | Since 1861. | —       | —          |
| 148.5        | 53.5        | 156     | 188        |

Comparing the amount of venereal at Gibraltar with the

\* Army Medical Blue Book for 1862, page 50.

amount in our army at home, it is usually made a subject of congratulation that it is so small at this station, "being repressed," as Dr. Parkes says, "by police regulations."\* It may be legitimately doubted, however, whether the amount of disease at Gibraltar affords sufficient cause for congratulation. It may be asked whether it is not with foreign stations, such as Malta and Canada, that Gibraltar should be compared rather than with England; and if this question is answered in the affirmative, then the above figures suggest quite other feelings than those of congratulation, and force us rather to lament that disease at Gibraltar should be in excess of what it is at the other two foreign stations. Comparing Malta before 1861 with Malta after 1861, we have seen that a great and permanent reduction of disease was effected through the enforcement of police regulations upon the women; but comparing Gibraltar, either with Canada, or with Malta before 1861, we might conclude that the system of police surveillance has not only not "repressed" disease at Gibraltar, but that it has had an exactly opposite effect, and has positively fostered it. But the problem is too complex to warrant hasty conclusions.

A similar inference as to the effect of "police regulations" on the amount of disease in England might be drawn from the following table, which gives the amount of venereal among the troops at home during ten years:—

Table No. 5. Troops at home.

|      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|
| 1859 | 1860 | 1861 | 1862 | 1863 | 1864 | 1865 | 1866 | 1867 | 1868 |
| 422  | 369  | 354  | 330  | 307  | 291  | 283  | 259  | 291  | 282  |

From this table we see that disease steadily decreased from 1859 to 1866 inclusive, while in 1867 it suddenly rose to as high a figure as that at which it stood three years before. The Contagious Diseases Acts were first put in force in the end of 1866, and the returns for 1867 give us the first result of one year's working of those acts. Perhaps it may be a mere accidental coincidence, but the fact is certain, that the sudden arrest in 1867 in the diminution of disease, (a diminution which had been steadily going on for eight years,) and its return to the higher amount of a former year, immediately followed the putting in force of the Contagious Diseases Acts. We shall more fully appreciate the change by examining the following table, which shows the amount of decrease in each successive year from 1860 to 1866 inclusive, and the amount of increase in 1867:—

|              |      |      |      |      |      |      |      |      |
|--------------|------|------|------|------|------|------|------|------|
|              | 1860 | 1861 | 1862 | 1863 | 1864 | 1865 | 1866 | 1867 |
| Decrease . . | 53   | 15   | 24   | 23   | 16   | 8    | 24   | —    |
| Increase . . | —    | —    | —    | —    | —    | —    | —    | 32   |

It is true that in 1868 there was not a further increase, for in that year, as will be seen from Table No. 5, there was a fall of 9. This fall, however, was exceeded in amount in every year before 1867 excepting one, and does not therefore require to be referred for explanation to the action of the Contagious Diseases Acts, unless indeed we thereby explain its unusual smallness.

### CASE OF INTRUSION OF A NEW SHILLING INTO A BOY'S STOMACH.

By R. LOCKE JOHNSON.

Visiting Physician to the Infirmary for Consumption and Diseases of the Chest, Margaret street, Cavendish square.

ROBERT S., æt. twelve years, having received his usual weekly stipend for services rendered as machine-boy in a printing office, placed in his mouth one of the shillings given him, in order to get it changed for coin of minor value before his arrival at the residence of his parents. Why he wanted change was this: a mutual arrangement had been entered into between his parents and himself, by which the boy was permitted to retain for pocket—

money 3d. per week, and his wages being even money, *i.e.*, five shillings, Master S. invariably secured his allotted pocket-money prior to yielding up the larger amount to his family, and for the purpose of this allotment he placed the shilling in the position stated. On the occasion under notice, not only the recognised threepence, but the entire shilling slipped into the wrong pocket, for Robert S., whilst on his way towards a friendly shop, where small change was occasionally given him, encountered a "fellow workman," who, to use his own words "squared at me in fun, then chucked my chin, so I threw up my head, and the shilling lobbed into my stomach."

The boy felt the shilling "glide down" freely, but suffered no inconvenience from it until the following day, when he experienced considerable uneasiness and some pain towards the pyloric orifice of the stomach. I ordered the boy to be supplied with plenty of well boiled vegetables, porridge, minced meat, bread and milk, &c., and to be permitted to enjoy himself out of doors freely. In thirty-four hours from the intrusion of the coin it was passed by him. He had two motions previously. No medicine was given until the coin passed.

A few years ago a girl, æt. eighteen years, accidentally swallowed a shilling. Oil pills and draughts were administered. The patient did not eject the coin until the eighth day subsequently, and in the interim suffered intense pain in the gastric region; was purged, restless, and very feverish. Bearing in mind that patient, and also in consideration of Robert S.'s age, induced me to treat his case herein set down, and the result has been, I consider, satisfactory.

## Hospital Reports.

KING'S COLLEGE HOSPITAL.

SATURDAY, JUNE 15.

(Under the care of Mr. HENRY SMITH.)

*Varicose Veins—Ætheromatous Tumour, removal of—Epithelioma of the Lip—Polypus of the Ear.*

MR. SMITH introduced to the class a man who had very extensive varicose veins; the long saphena could be traced from the side of the great toe to the opening. Many other veins were also much enlarged, and there was a large bag of veins on the inner side of the popliteal space. Mr. Smith passed about thirteen needles under the more prominent, and applied the twisted suture. Mr. Smith afterwards remarked that all ordinary treatment having failed, together with the fact of the man's life being in constant danger lest the vein gave way, he felt quite justified in operating, and, moreover, he had had as severe a case before which had got perfectly well by this procedure.

The ætheromatous tumour removed by Mr. Smith was a small one, situated on the face of an infant. He carefully dissected it out, removing the whole of the sac, and then applied a pad and bandage. These cases he observed generally did well, *but the sac must be removed, or the disease would recur.*

The case of epithelioma of the lip was situated on the lower lip of a man, whose appearance denoted fair health, and, moreover, there was no enlargement whatever of the neighbouring glands. Mr. Smith made a V-shaped incision, removing with the diseased portion a good margin of healthy tissue; the edges of the wound were then brought together with pins and the twisted suture-dressed in the ordinary method, and painted over with collodion. Mr. Smith remarked:—1st. On the circumstance of the man bearing the operation without flinching—chloroform not having been administered. The ability to bear pain seemed to him to be granted in a greater degree to some

men than others, though the possession of this power by some men was opposed to the views of physiologists, who maintained that the same intimate structure of tissue was common to mankind in general. 2nd. The case was a most favourable one for operation, inasmuch as there was no implication of adjoining structures; and 3rd. In performing an operation similar to this, it was of the utmost importance to take care that the whole of the disease was cut out, and consequently he had removed a considerable portion of healthy tissue also. This procedure was perfectly justifiable for the reason already given, and, moreover, the extreme elasticity of the lip rendered the healing of the wound not only easy, but the deformity afterwards was very slight. The case was just one of those of which you might predicate a successful cure.

Mr. Smith then removed a polypus from the ear. Great care he said was necessary, as if force were applied, and the patient happened to move, the tympanum might be injured; moreover, you ought always to be careful, and seize the pedicle.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

JUNE 27TH, 1871.

#### REPORT OF THE COMMITTEE ON VACCINO-SYPHILIS.

THE following are the cases (of the first series reported on April 25th) which the Committee have had an opportunity of seeing through the courtesy of Mr. Hutchinson:—

Vaccinifer No. 1, female, aged seven months. Had been used on February 7th for vaccinating the series of cases reported by Mr. Hutchinson on April 25th. This child is hydrocephalic; its head is much elongated and widened posteriorly; the fontanelle is somewhat more open than usual. It is pallid, but not unhealthy looking. There are five marks on the left arm from vaccination, which are quite healed. No eruption can be seen anywhere; the arms and genitals are quite clear, but the mother states that there were sores on the latter after vaccination. The glands in both groins can be distinctly felt. The mother is rather pale, but looks healthy, and declares she has always been so. This is her first child.

The following persons were vaccinated from the preceding case on February 7th, and presented on May 16th the following features:—

1. Female, aged seventeen, a hearty, robust, plump girl, with bright colour. Has three vaccination marks on the left arm in a horizontal line, the outer of which is not yet healed. The base of this sore is very slightly thickened. Mr. Hutchinson states that this girl has been living at home with her friends, and taking her medicine very irregularly.

2. Male, aged eighteen, assistant to a stationer in Westminster. A dark-complexioned, strumous looking lad. Has three cicatrices on his left arm, which present nothing different from vaccination marks. There are a few small scattered spots of acne on the shoulders and upper part of chest.

3. Male, aged nineteen, a warehouseman in the City, a healthy-looking lad. Has an unhealed ulcer, larger than a shilling-piece, on the right arm, resulting from vaccination. The sore is covered by a crust, which is disposed to scale slightly, and its base is leathery. Nothing else can be detected.

Mr. Hutchinson states that this is the last case traced of the series related on April 25th, and therefore treatment was commenced later than in the others. He also informs us that in the above three cases the vaccination sores all healed, and subsequently ulceration set in at some of them, which continued to spread slowly until mercury was given, when in about ten days they commenced to heal. Black wash was applied locally. The same sequence of events occurred in all the other cases of this group.

From the foregoing account it will be seen that neither the

vaccinifer, nor any one of the three cases vaccinated from it, presented any symptoms of constitutional syphilis at the time of our examination. But whilst in Case No. 2 the vaccination sores were healed, leaving nothing but the ordinary scars, in cases Nos. 1 and 3 there were still open ulcers at the site of the vaccination fourteen weeks after its performance. These ulcers were of a suspicious, but not of a conclusive, character.

Of the second series reported by Mr. Hutchinson in an appendix on May 9th, we have seen the vaccinifer No. 2, and three children vaccinated from it.

Vaccinifer No. 2, male, aged seven months. Had been used on February 13th for vaccinating the series of cases reported by Mr. Hutchinson on May 9th, and brought under his observation by Mr. Warren Tay. This child is hydrocephalic; its head is universally enlarged; the fontanelles are perhaps more open than usual. It is a pallid, delicate-looking child, and has a slight herpetic eruption on the forehead, but is very lively. It breathes hard through the nose; the mother says it has a cold and is teething. There is a small white scar at the anus as if from an ulceration. The glands in both groins are large and separate. On the right arm are five vaccination marks, which are all healed.

The mother is a bright-complexioned, healthy-looking woman. Has never suffered from illness. This is her first child. She has never had a miscarriage, or discharge, or sore nipples. She says the child has been occasionally nursed by the landlady and her children. She knows that one of these was ill, and sent to Croydon for its health, and that the mother had attended a hospital in the Hackney road, but she never heard what was the matter with either of them.

The father, aged twenty-seven, cabinet maker, is a spare, pale man, but apparently in health. He had worked thirteen years in the same situation. He denies having had venereal disease of any kind, and readily submitted to examination without previous preparation. Nothing could be found except some enlarged separate glands in the left groin, and a slight white scar on the inside of the cheek opposite to the left molar tooth. The only illness he has ever had are measles and whooping-cough.

The following cases, which had been vaccinated from vaccinifer No. 2 on February 13th, presented the appearances detailed below on May 16th—thirteen weeks afterwards:—

1. E. T—, aged four years and a-half, female (No. 2 in Mr. Hutchinson's second appendix). A pallid, thin, strumous-looking child. On the right arm are two sores covered by crusts. The larger of these has a circumscribed thickened base, which is superficial, and has a leathery feel when compressed; the surface of this is disposed to scale. The glands in the corresponding axilla are enlarged. There is a scaly eruption, consisting of small, circumscribed, for the most part circular spots, of a copper colour, at the back of the neck, the lower part of the abdomen, and the upper and outer part of the thighs; with a general scattered mottling of the trunk on its anterior surface especially. The inguinal and post-cervical glands are large and distinct. Both the tonsils are excavated, but not now ulcerated.

2. A. E. T—, aged eighteen months, male (No. 1 in Mr. Hutchinson's appendix). A fat, well-grown, hearty-looking boy. On the left arm are two large dusky-coloured marks of vaccination, which are scaling on the surface, but not ulcerated; these have a thickened base precisely similar to the preceding case. There is a general mottling of the trunk, which is fading, and a few small scaly spots resembling those in foregoing patient, and scattered over the abdomen. The glands in each groin are very distinct. There is well-marked ulceration of both tonsils.

The mother of these children is a healthy-looking woman. She had not suffered from illness. A rigid cross-examination failed to elicit any history of previous syphilis in herself or either of her children.

3. W. C—, aged ten, male (No. 3 in Mr. Hutchinson's appendix). This case was not reported at the Royal Medical and Chirurgical Society). A spare lad, but not unhealthy in appearance; his mother says he has lost flesh lately. On the left arm the cicatrices of vaccination in infancy show plainly, and below these are two large sores covered with crusts, with well-defined thickened circumscribed bases, surrounded by a dusky areola. The glands in the corresponding axilla are enlarged. The inguinal and post-cervical glands are very perceptible to touch. There is a scaly eruption, for the most part

in small annular patches, over the trunk and limbs, which is fading. On each tonsil is a deep vertical ulcer, with a grey unhealthy surface.

The mother is a tall, healthy-looking woman. She has never had any serious illness, and no history of previous syphilis in herself or her boy could be obtained. These three cases were vaccinated on the same day, and the ulcers resulting had never healed, but have slowly increased in size. There has been no treatment in any of them.

In our opinion these three cases present unequivocal evidence of constitutional syphilis, and we see no reason to doubt, from the appearances presented by the arms, and from the history of the cases, that the disease had been conveyed by vaccination.

As to the method in which vaccination was performed in these cases, and the character of the fluid inoculated, whether lymph, blood, or both, we could obtain no satisfactory evidence, and with regard to this question we may refer to the remarks made by Mr. Hutchinson in the appendices to his paper, where such facts as could be elicited are recorded.

(Signed) SAMUEL WILKS, GEO. G. GASCOYEN,  
WM. S. SAVORY, THOMAS SMITH.

The following case was shown to Dr. Wilks by Mr. Hutchinson on May 19th, being one of the second series:—

4. Female, aged fourteen (No. in Mr. Hutchinson's second appendix). There was a round red sore on the arm, raised and granulating. Over the body and arms was a well-marked eruption of bronze-coloured, scaly, raised spots. The tonsils were swollen, and slightly ulcerated.

(Signed) SAMUEL WILKS.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 26, 1871.

### THE CONTAGIOUS DISEASES ACTS.

THE Report of the Royal Commission has been the signal for so much new controversy and for such a strange display of feeling, that we must ask our readers to consider for a moment two or three separate events in connection with the matter.

Just before the issue of the Report in reply to Mr. Baines, Mr. Bruce said the report of the Commission would be in the hands of the members in the course of a few days. It was signed by twenty-three of the twenty-five members, two being absent, one from illness and the other on duty. The number of dissents detracted

from the unanimity of the report. Two-thirds of the members were in favour of qualified compulsory application of the Act, one-third (or rather, seven) were in favour of strengthening rather than weakening the Acts; six were in favour of repealing all compulsory legislation, and all were in favour of further legislation, with a view of modifying the law to make it applicable to the whole country. Such a report was intended for the information of Government, of Parliament, and of the whole country; and at this period of the Session it would be impossible for hon. members to give due consideration to the report so as to be able to pass a useful measure founded upon it. It was, therefore, not the intention of the Government to introduce a Bill. (Cheers.) Strong feelings had been created in the public mind by the repetition of statements that in carrying out these Acts outrages had been committed upon innocent and virtuous women; and those statements had not been confirmed. Had they been confirmed, it would have been the duty of the Government, under any circumstances, to repeal Acts capable of such abuse; but the Commissioners said that the result of inquiry was to satisfy them that the police were not chargeable with any abuse of authority, that they had discharged delicate and difficult duties with moderation and caution, and that there was no foundation for the charges which had been so rashly made and repeated, and which had contributed to excite public indignation against these enactments. That finding was unanimous, and an examination of the facts showed not only that many of these statements were gross exaggerations, but that the greater part of them were sheer inventions. (Cheers.) The House would therefore see that the substitution of legislation for that now in force was a matter which required on the part of the Government deep and anxious consideration, which could not be given to it either by the Government or by private members at this period of the Session.

As soon as the report appeared a conference of representatives of the various branches of the Association for the Repeal of the Contagious Diseases Acts was held. There were a very large number of ladies present. The Chairman considered that the Royal Commissioners, had issued a weak and vacillating document. He referred to the clause recommending that all licensed victuallers harbouring prostitutes should, upon conviction, forfeit their licenses, and to that recommending the abolition of compulsory and periodical examinations. He condemned the conduct of Mr. Bruce in respect to the Act of which they complained, and considered that they should declare that nothing would satisfy them but the total and immediate repeal of all the obnoxious Acts, including the Act of 1864. Dr. Guthrie, of Edinburgh, then read a memorial, requesting the Government to take steps during the present Session to repeal the whole of the obnoxious and immoral Acts known as the Contagious Diseases Acts. He said, so strong did he feel upon this question, that he was prepared to sacrifice party for the purpose of obtaining the total repeal of those disgraceful Acts. He considered the ladies who had taken a prominent part in this movement had covered themselves with great honour. The memorial was almost unanimously adopted.

After this a deputation, extraordinary in its character, composition, and conduct, waited upon Mr. Bruce at the Home Office. The *Times* thus describes the gather-

ing:—"The male portion of the deputation consisted of members of different religious bodies and persons said to represent various towns, while the female portion was constituted of young, middle-aged, and elderly women, apparently eager to enter into discussions on the subject, and who gave the most unremitting attention to the proceedings."

Mr. Fowler, M.P., in introducing the deputation, said that the very existence of the Liberal party depended upon the manner in which this subject was dealt with. (Loud cheers.)

Mr. Bruce.—I must tell you that this is not a public meeting. I shall be happy to hear your views, but you must not conduct these proceedings as if you were in a public meeting.

The Rev. Dr. Guthrie declared that unless the Acts were repealed the subject should be brought to the knowledge of every household in the kingdom; and he expressed himself as horrified at the literature which Christian men and women, who were loyal subjects, would feel it their duty to send broadcast.

The Rev. Dr. Rigg believed that if the Acts were not repealed the people would have to be made to understand the subject, even at the hazard of the matter being discussed by women and children.

Several other persons broke the limit drawn for speakers and insisted on continuing the discussion.

Mr. Bruce said at length—I assure you that I have other engagements before I go to the House, and I have now but little time to spare. It certainly strikes me as peculiar that the opposition to these Acts—the strongest opposition—should come from places the furthest removed from the towns where the Acts are in operation. (Murmurs.) I cannot but express my regret that the advice of Mr. Otway was not followed, and I think it is in the worst possible taste to make attempts to influence me by appeals to my own interests. I am here as representing the Government, and it is, to say the least, wrong to attempt to induce me by appeals to private motives to take a certain course. Of this I have no doubt, but further legislation of a repressive character is needed—legislation which may put an end, as far as legislation can, to certain immoral practices, and thus save many unhappy women from the course which they now adopt. The Government, feeling that to attempt to repeal these Acts without a substituted measure would not only be dangerous, but would be impossible in the present state of the Session, I appeal to the members of Parliament here whether, supposing the Government were desirous to carry the repeal of these Acts, it would be possible to pass such a Bill through the Legislature? Well, now, the Commissioners were men capable of inquiring, and with full powers, and yet they report—and this is unanimous,—that there is no evidence whatever to justify these statements of interference with liberty by the police. Well, they are gentlemen of truth and honour, and I would set their honour and truth against the honour and truth of any three-and-twenty gentlemen, and they signed the report to the Queen that, having given every opportunity to have these statements justified, none had been proved. (Confusion and murmured remarks.) If the outrages alleged to have been committed under these Acts had been proved there would have been abundant reason for abrogating the law, but this reason did not exist.

Those who have been readers of the MEDICAL PRESS AND CIRCULAR for the last year will certainly not accuse

us of failing in liberality of opinion in respect of the Contagious Diseases agitation. The expression of opinion may therefore come with some force from us when we say that proceedings like this are scandalous, disreputable, and unconstitutional. The only effect they could have on any conscientious or powerful Government would be to give birth to a determination not to submit to such bullying.

It is stupid and foolish for a crowd of agitating women to constitute themselves the exponents of thoughtful reformers—it is, in the highest degree, unwise for them to adopt this highwayman's challenge to the Government. But it is still worse (and we are astounded to read such words from the lips of Dr. Guthrie, of Edinboro') to try to carry their point by means of a threat to let loose the indecencies of prostitution and syphilis propagation in "every household in the kingdom."

---

## SCOTLAND.

### EDINBURGH.

**THE FEMALE STUDENTS.**—At a meeting of the lecturers at Surgeons Hall it was resolved by a majority of votes to rescind the resolutions passed last summer granting permission to female students to attend the courses of lectures delivered there. This prohibition does not extend to those lecturers who give instruction to women desiring to qualify as nurses.

THE sum of £200 has been given by a lady towards the establishment of a Woman's Hospital in Edinburgh.

### ABERDEEN.

A DEATH from chloroform is reported as having occurred in Aberdeen Dispensary.

---

## Notes on Current Topics.

### Detection of Blood Stains.

AN American contemporary says that iodide of potassium dissolves traces of blood, even from clothing which has been thoroughly washed, but hæmatin crystals cannot be obtained from the solution.

Gunning has discovered, in the acetate of zinc, a reagent that precipitates the slightest traces of the colouring matter of blood from solutions, even where the liquids are so dilute as to be colourless. Blood washed from the hands in a pail of water can readily be detected in this way. The flocculent precipitate, thrown down by the acetate of zinc, must be washed by decantation, and finally collected on a watch glass, and allowed to dry, when the microscope will readily reveal hæmatin crystals, if any blood be present. This test has been repeatedly tried with entire success.

### Epidemic among Horses.

THE *New York Sun* says—Within a few weeks past an alarming and fatal malady has made its appearance in the stables of some of the city railroad lines in New York. By some it is pronounced to be cerebro-spinal meningitis. The first symptoms are manifested in the slow, sluggish movement of the hind quarters, and in stumbling. It is a disease of the membranes over the spinal marrow, and

beginning apparently over the lumbar vertebræ, effectually paralyses the hind quarters. The distemper gradually works itself along the spinal cord until at last it reaches the brain, when the fore legs give way, and the horse is deprived of the use of his limbs. The most remarkable feature of this disease in its present aspect—one in which it differs from the real cerebro-spinal meningitis—is that the horse continues to eat and drink as heartily as though he was well, his appetite seems to increase rather than diminish as the disease advances. If the horse, when stricken with the disease, is allowed to lie down, he will never get up. Therefore, just as soon as numbness in the hind quarters is noticed, the horse is supported by broad canvas bands, and as soon as he is able to stand he is turned loose. In some localities it has swept over the country as a curse, paralysing in a day the farmer's finest stock. The poor truckman, too, who is so dependent upon his horse for his livelihood, has not been exempt from the ravages of this epidemic, but in a few hours has been obliged to see his horse stricken down helpless and die.

### The Abuse of Medical Charity.

A LARGE deputation, representing three important organisations, had an interview with Mr. Stansfeld, on Tuesday, in relation to the present system of medical relief of the poor and the abuse of the dispensary system. Sir Charles Trevelyan and other gentlemen attended for the Society for Organising Charitable Relief; Mr. Corrance, M.P., Mr. Kennaway, M.P., and other gentlemen, attended in connection with the Metropolitan Branch of the British Medical Association and the Poor-law Medical Officers' Association. Sir Charles Trevelyan opened the proceedings by stating that at a conference of the medical profession held under the presidency of Sir William Fergusson, when no less than 156 members of the profession were present, resolutions were passed condemning the existing system of gratuitous medical relief, and looking for an improved condition of things to the establishment of provident dispensaries. The medical profession then formed four committees, and their reports and resolutions Sir Charles laid before Mr. Stansfeld. The deputation asked for the assistance of the Poor-law Board in encouraging the establishment of provident dispensaries, in discouraging free medical out relief, and in placing the out-door medical relief under the Poor-law Board. The conference lasted nearly two hours. Mr. Stansfeld said he was most desirous of meeting with members of these societies, for the purpose of discussing these questions. He was convinced of the evils of which they had spoken: and he well knew the value of voluntary effort in aid of the legal or regular forces in lessening those evils. Their opinion, as he gathered it, was that there should be no gratuitous medical relief except under the Poor-law Board. Several voices affirmed this view. He pointed out that the Poor-law Board could not control the free action of institutions supported by voluntary subscriptions, and that this could only be done by appealing to the public, and by influencing the organs of public opinion to stop such evils by exposing their dangers. He stated that the Poor-law Board was proceeding to urge forward the dispensary system in town under the Act of 1867, and even in the country, where the Board had no power of enforcing its views on this point as yet, the system was being adopted by guardians, whom he had found generally willing to take advice.

Speaking of a proposed "general system," he expressed his confidence in a local rather than in a centralised system, and he thought that though local action caused some delay sometimes, yet that, on the whole, it worked better than the over-ruling and over-governing found in a centralised system. He quite agreed as to the necessity of the provident dispensary system, but said it rested with the public. The deputation thanked Mr. Stansfeld and Mr. Hibbert, M.P., for their attention, and withdrew.

### Meat Preserving Competition.

THE *Melbourne Argus* informs us that an interesting competition between the meat-preserving companies of Victoria and the Admiralty manufacture carried on at Deptford has taken place. The object was to compare, under equal circumstances, the Victorian meats with those preserved under Admiralty auspices. The competition may be said to have arisen out of a judgment passed by the Society of Arts. That body having had submitted to their criticism certain tins of meat preserved by the Melbourne Company, taken at random from the stores of the company's London agent, sent to the Deptford dockyards, for preserved meat wherewith to compare the colonial sample. There decision was that the Melbourne Company's meat was excellent, and only just inferior to the Deptford meat, to which expression of opinion the Melbourne Company strongly demurred, because their meat had been taken at random, while the authorities at Deptford had had ample opportunity to specially prepare for the comparison. At the request of the agent-general the Admiralty authorities caused six cases of Deptford preserved boiled beef to be sent to the Victorian Government as a sample. A circular was issued from the Victorian authorities to the various meat-preserving companies inviting them to send in samples of their meat. The samples were stowed away for more than six months in the Custom house. The various tins were sent in to the judgment chamber with their labels obliterated, and simply numbered, so that no obvious means of identification were afforded. The Government appointed a day on which the tins should be opened, and a number of gentlemen were nominated to sit in judgment. Mr. Moody said it was not till after a full decision had been come to that any of the judges knew on whose manufacture they had passed their opinion. The decision of the Committee was that they considered the meat in Nos. 2 (Melbourne Meat-preserving Company), 4 (Echuca Company), and 5 (Warnanbool Company), as excellent in all points. The meat in the No. 3 (Ballarat Company) tins was slightly over-cooked, but otherwise good. The meat in the No. 1 (Deptford) tins was decidedly over-cooked, and, in the opinion of the Committee, therefore objectionable, but the meat was sound.

### Health of Dublin.

IN the Dublin district the births during the week ending July 15th amounted to 157. The average from the years 1864 to 1870 was 158. The deaths registered during the week were 103. The average of previous seven years was 106. Four deaths were caused by fevers, viz., two by typhus, and two by typhoid. Scarlet fever proved fatal in two instances, and small-pox in one. Croup was the cause of two deaths, and eight were ascribed to convulsions. Four deaths resulted from pneumonia, and but one

from bronchitis. Two deaths were referred to apoplexy, four to heart disease, and two to aneurism. One death was attributed to Bright's disease, and to kidney disease unspecified two. Nineteen persons fell victims to phthisis, two to mesenteric disease, and one to scrofula. Three deaths from cancer were registered. Four deaths were the results of accidents.

#### Dyte v. the St. Pancras Guardians.

It is really time that medical men stood "shoulder to shoulder," when we notice the shabby way in which public bodies of men treat the most able and hard-working amongst our fraternity. In the *St. Pancras and Holborn Journal*, of July 15th, we notice that Mr. Dyte, the able officer of the Jewish Board of Guardians, in Bishopsgate, who was appointed to the post of Medical Officer to the Highgate Infirmary for some time, and suddenly removed from his post in order to make way for a gentleman, favoured by some one of the parties which make up that famous Board of Guardians, has naturally demanded some pecuniary satisfaction for a dismissal which was quite unexpected by him. The defendant Board acknowledges the ability of their late medical officer, but states that it is not indebted at all to Mr. Dyte, although it comes out in evidence that they had given that gentleman to understand that he was to be retained in his position for some longer period. In point of fact, the Board, seeing how far they fail in establishing their case on the grounds of justice and equity, wish to strain in their favour whatever legal technicality may be left to them. Not a moment too soon has arisen the agitation in favour of Poor-law Medical Reform, when such cases as that of our able *compère*, Dr. Dyte, can occur under the present system of nomination. A subscription to enable Dr. Dyte to carry on the case has been opened, and Dr. Woodman, of the London Hospital, receives subscriptions.

#### Protection from Poisoning in England.

THE Pharmacy Bill, after having passed the House of Lords, and achieved its first reading in the Commons, has submitted to the inexorable demands of the Army and Ballot Bills, which have devoured almost the entire legislation of the year, and it has been withdrawn. We deeply regret this result, for we fear the protection of the public from misadventure may be seriously endangered thereby. Before the next meeting of Parliament, the Government which has pledged itself to effect this necessary and just reform, may have died, and its successor may want the votes of the druggists. Mr. Forster, who has taken the matter in so firm a hand, may probably be translated, in the style of the present Government, to a bishopric, or constructorship of the navy, or some other office of which he is utterly innocent, and the sailor or lawyer who may be selected to succeed him at the Privy Council, may possibly not care whether or not Her Majesty's lieges are poisoned occasionally. Moreover, the druggists will have time to organise a barricade, and we know by the anti-vaccination and contagious diseases agitations, that there is no opposition too ridiculous to effect its object, if it be only pushed, without scruple, through the medium of indignation meetings and newspaper paragraphs.

Mr. Forster makes rather a poor show just now. He talked very loud, and blustered a good deal, and now his

superior officer, without hesitation, puts a stop to his threatened onslaught. Meanwhile, we are encouraged to see that the "Party of Order," who have voluntarily adopted precautions against poisoning, and don't wish to be slovenly, are coming to the point, and the *Pharmaceutical Journal* is, after the example of the *Times*, throwing out feelers for a change of policy from opposition to adhesion. A letter in favour of the amended Bill is published in that periodical this week, and it bears the signatures of almost all the large respectable chemists in London, and many in the country. Thus the opposition is narrowed to the limits of the small retail druggists, and loses so much of its force that we have reason to believe that it will lack power eventually to defeat the reform.

#### Professional Evidence.

A CASE was tried last week at Portsmouth which discloses, in a most marked degree, the serious differences which prevail when members of the Profession are called upon to give evidence before a jury. Excuses have been allowed in some cases, and with reason, for this unsatisfactory state of things, particularly in cases of railway or other accidents; but that there should be such strange divergence of opinion upon the effects of the commonest drugs upon the system, as in the case before us, in which a solicitor is charged "with administering certain noxious drugs to the person of a young lady, thereby producing abortion," is, we confess, the very reverse of creditable.

We might be accused of very strong language if we ventured to remark, that the opposition of *sides* caused a member of the Profession to forget the honour due to it, to himself, and the public for truth's sake. But the expression of such views upon the conduct of medical men in our courts of law is very common indeed outside of professional circles, and it is well sometimes, even at the risk of giving offence, that we as journalists should boldly draw aside the curtain, and in the name of our common right to an honourable profession, and our title to that of gentlemen, ask why these things should be? We know of hundreds of instances where our brethren have yielded to no equivocation in cases which offered the most tempting pecuniary inducements. But with these we have not now to do. We ask why there are any exceptions?

#### Our Population and its Increase.

THE enumerated population of England and Wales living at midnight on April 2nd, 1871, was 22,704,108 souls. This is an increase of 2,637,884 over the numbers living at the last census, and exceeds general expectations, for the increase from 1851 to 1861 was 2,138,615, and the rate of increase was 12 per cent. in the ten years that ended in 1861; whereas the rate of increase in the last ten years has been 13 per cent. When we add to the population of England and Wales that of Scotland, Ireland, and the Channel Islands, with a provisional return of British subjects abroad, the whole numerical strength of the United Kingdom may be taken at 31,817,108 persons, of whom 15,549,271 were males, and 16,267,837 females.

THE Emperor and Empress of Brazil, in company with Dr. Acland, inspected the Radcliffe Infirmary, Oxford, on Saturday last.

### Medical Evidence.

WITH shame we quote from the *Standard* the following remarks in reference to the evidence of Drs. Jackson, Haynes, Walton, and Gay, for the defence of Mrs. Newington *alias* Davey:—

“The necessities of the defence did but furnish another proof of the worthlessness of what is known as the testimony of experts. Mrs. Newington’s medical witnesses were open to the remark that they were speaking less with reference to the ascertained circumstances of the case than to frame a theory of their own which might justify a verdict of acquittal. We can understand the embarrassments of their position, but we cannot approve their way of extricating themselves from them. We are willing to accord all due weight to scientific opinion, but we consider it a misfortune, alike for the public and for the savans, when it becomes evident that such opinions may be obtained by any one who is willing to pay the market price for them. In actions for damages this is quite bad enough, but it is infinitely worse when the same means are employed at inquiries consequent upon the deaths of those who have gone to their last account, and which intimately concern the lives and limbs of all whose evil hap it may be to suffer from excesses of ungovernable passion and the outbreaks of lawless violence.”

We express no opinion as to whether or not these observations are applicable to the case to which they are applied, but we cannot but admit that this and much more might truly be said of medical evidence generally. What a disgrace to our Profession is involved in the statement that their sworn testimony may be obtained by anyone “who is willing to pay the market price for it.” We are well aware that medical witnesses do not sell their honour with their evidence, but it is patent that instead of setting themselves dispassionately to investigate a case, and testifying thereon the unbiassed truth, they are wont to set themselves to find out facts for the support of a favoured theory, and then swear their *ex parte* ideas as if they were skilled opinions.

A SON of Professor Humphry won the Queen’s Prize at Wimbledon.

THE *Gaulois* alleges that a considerable fall has taken place in the level of the ocean in consequence of the tropical heat!

A CASE of small-pox was landed, on the 16th ult., at Portland, from H.M.S. *Seamew*, and was taken to the Government hospital. Cases of small-pox are being brought into Shields by shipping.

CHARLES DE BUDDELY and his wife, the medico-botanical abortionist, and the clairvoyant, whose career we noticed some weeks since, have been sentenced to twelve months’ imprisonment and hard labour.

THE health of the Wimbledon Volunteer Camp is unusually good this year, the medical superintendents being Surgeon-Major Wyatt, Dr. Mayo, of the Inns of Court R.V., and Assistant-Surgeon Temple, V.C. Since the camp was established there has been an average number of 2 600 men under canvass, not one of whom has been sent away in consequence of illness. There have been a few cases of rheumatism, and one or two of diarrhœa, with two or three patients in hospital from trifling accidents.

PROFESSOR SAYRE, of New York, has been quite startling it amongst us in London. He has lectured to most attentive audiences, and demonstrated his mode of treatment of disease of hip-joint at several metropolitan hospitals.

MR. RAWLINSON, C.B., has written to the *Liverpool Daily Post*, and says the report of Drs. Parkes and Sanderson, on the sewers of Liverpool, is “misleading and dangerous to the health of Liverpool.” He says that it is a mistake that sewers require no ventilation, and that all covered sewer shafts ought to be *un-covered* for ventilation, and the sooner the better.

WE would recommend our readers, and, indeed, society in general, to follow the sensible example of the Emperor of Brazil, who rises early and takes morning drives in the suburbs. If we were to follow the example of our ancestors in the matter of early rising, our health would be better, and our work done before the heat of the day.

WE would put those who are leaving town on their guard against taking infected apartments at the seaside or in the country. The danger of contracting infectious diseases is especially great this year, by reason of the late epidemic. All who are about to leave London should be vaccinated.

AT a late meeting of the Council of the Royal Medical Benevolent College, the Rev. Dr. West spoke of the desirability of introducing lay boys, which had hitherto been impossible by want of funds. Mr. Erasmus Wilson offered to erect, at his own expense, a suitable building for their reception, the estimated cost of which will be £3,000.

LAST week H.I.H. the Crown Princess of Prussia, attended by her suite, visited the German Hospital at Dalston. She was received by the staff, and inspected the hospital. She expressed an opinion that, for sanitary reasons, bed curtains were better dispensed with in a hospital. She was otherwise very pleased with the arrangements.

FIVE companies have recently been started for supplying bituminous paving asphalte or noiseless pavement, so that we may hope soon to have our streets covered with it, and the rattling over the stones, at present so annoying, be dispensed with for ever. Better provision should, however, be made for cleansing it, as it forms a disagreeable dust in windy weather, and a slippery slide in wet weather.

THE Manchester Anti-vaccination League held their annual meeting last week. Among the letters of apology for non-attendance was one from Sir Thomas Bazley, M.P., who wrote saying he was “really very sorry to differ from the anti-vaccinators on the question of vaccination.” The Bishop of Manchester and Mr. Hugh Birley, M.P., also held opinions opposed to the league; and Mr. Jacob Bright, M.P., while offering facilities for vaccination, would at the same time take greater precautions than any that have yet been taken to have it well done and to guard from injury.

In consequence of the Asylums Board having provided more accommodation for small-pox patients, the two iron hospitals in Marylebone have been closed. Dr. Whitall has drawn up a report, from which it appears that the old iron hospital was opened January 11th, a second, February 10th, each having plenty of room for thirty beds. They remained open up to June 24th. During a period of twenty-four weeks 215 small-pox patients were admitted. The number of deaths was 39. Of the cases, 190 had been vaccinated, 4 inoculated, and 41 neither. Of those who died, 20 had been vaccinated and 19 had not. Dr. Whitmore suggests a number of temporary iron hospitals. The cost of each patient is about 23s. per week, including all miscellaneous expenses.

## HOMŒOPATHY—ITS PRINCIPLES EXPLAINED.

(Continued from page 36.)

THIS, then, is Dr. Epps's answer to the question—"What is Homœopathy?" "It is the administration of remedies to assist life in its struggle, and such remedies as cannot be at all dangerous or unpleasant." In other words it is giving something which is perfectly harmless and not at all disagreeable to take. But conscious that the question is not thus answered, he goes on to say what it is by comparison. He tells us that there are three modes of administering medicines. (Are these remedies?) The antipathic, the allopathic, and the homœopathic. The antipathic (*αντι* and *παθος*) mode is to give medicines capable of producing symptoms opposed to the disease; the allopathic (*αλλος* and *παθος*), or counteraction induces the disease to change its locality, or simulates natural metastasis; the homœopathic (*ομοιος* like, and *παθος*), is to give medicines which produce the same or a similar disease to that for which it is administered. As an illustration, he says, "the antipathic mode is to put out a fire by heaping damp materials on it." It would have been more correct to have said "by throwing water on it." The allopathic "is to light a fire in another place." Again his reason is defective. The object of counteraction is not to get two fires to burn together, but to transfer the original fire to a place where it cannot do mischief, or where it is under our control. That this is often done by nature, and may be imitated by art, is well understood both by the Profession and the public. The homœopathic mode is to add fuel to the flame. That this is their doctrine there is abundance of proof in the "Organon of Hahnemann" or the Homœopathic Bible. It is easy to perceive that the illustration does not apply well on account of the difficulty there would be in removing a fire.

The following examples may assist:—

If a team of horses cannot move their load the antipathic mode would be to get another horse in addition; the allopathic to lighten the load; the homœopathic to add more weight to the load. Or, let a flock of sheep represent the patient and a savage wolf the disease, the antipathic mode would be to destroy the wolf; the allopathic to take the sheep out of the way; the homœopathic to let loose another wolf. Or, leaving metaphor and coming to the exact province of medicine, let us take an instance of poisoning—the antipathic cure would be by administering chemical antipotes; the allopathic to use the stomach pump; and the homœopathic to give more of the poison. Reader, take your choice.

It is not to be supposed from the above that some practitioners use the antipathic and others the allopathic mode of cure. The division is quite a gratuitous one on the part of homœopaths and has never existed. We are neither slaves of a system nor avowed followers in every case of one fallible mortal; but homœopaths tell us Hahnemann was infallible, just as some tell

us the Pope is infallible; and surely it would be worthy of consideration whether they could not borrow a further idea from the Papacy. Would it not be well to have a successor to Hahnemann just as they have to St. Peter? Many discrepancies would thus be abolished. We should not have one homœopathist uphold bleeding, another counter-irritation, another external application (all of which are denounced by Hahnemann) unless Pope Hahnemann (or Epps) the Second issued a bull allowing them to do so, and annihilating the decree of his predecessor. Under the gracious superintendence of the successor to their oracle they would surely be of one mind, and their internal dissensions and discrepancies be no longer visible to a discerning public. Still Dr. Epps insists on contrasting these several modes, and thus proceeds:—

"*Antipathy.*—If a person is sleepless, opium, which induces sleep, is given; if a person has excruciating pain opium or some substance having a stupefying power is prescribed; if a person is constipated purgatives are given; if persons have relaxed systems astringents or binding substances are administered; if persons have strong and excessively rapid pulse and circulation blood is withdrawn."

Now, although we might here remark that all antispasmodics are not stupefying, and that no physician acts in the blind way Dr. Epps represents, we would we could stop for an instant upon this subject, that the public may not be led to depreciate or fear valuable remedies from the untruthful representations (we should rather say misrepresentations) of Dr. Epps. Opium, although a powerful poison, and in the hands of the ignorant likely to do mischief, is in the hands of a skilful man by no means the pernicious drug the doctor has found it. He states that the patient is invariably worse after its exhibition. If the Doctor has been in the habit of giving it in improper cases he has doubtless found this the case, but place beside his evidence that of Dr. Todd, who says that "in traumatic delirium when sleep is procured, which may be done by a judicious use of this invaluable agent, the patient recovers." The other cases in which it is useful may all be justified by reason and experience; and so of every instance the Doctor gives. But homœopathic reasons (in more senses than one are they so), tell us that all that men have done for the relief of suffering humanity has been worse than nothing, for they have spent our lives in killing rather than in curing; and to back the mendacious insult bid us lay by all our experience—put away the testimony of all men of all ages, to count Hippocrates a madman, Sydenham a fool, and all their followers extortioners and liars. And what do they offer us in its stead? A German importation just in its cradle, with one Hahnemann its founder! whom they style the "star of truth," and into the bargain their own experience as to the efficiency of infinitesimal doses. Such is homœopathy! But at present we have only penetrated the outside of this bewildered maze. Let us proceed further. We are determined to penetrate its thickest parts, and hope to come out uncontaminated by the folly of those who follow the dreams of a solitary enthusiast to the total exclusion of either philosophical, experimental, or medical science."

The Doctor next assails what he calls "Allopathy," or "Counteraction." He tells us of cases where it only produced temporary relief, and affirms that in every case it "exhausts the vital powers," and so shortens life. Here, again, we totally disagree with him. We cannot tell with what minute investigation he may have endeavoured to decide how much shorter time a man lives for having had a mustard poultice to his chest than he who has not, but we are quite sure that counteraction has saved many a life and is likely to save many more. For a total refutation of his remarks on allopathy we may refer our readers to a work published by this same "John Epps, M.D., &c.," in 1832, in which he advocates the principle of "Counteraction." When he indulges

in imagination his words become so untruthful as to be beneath notice, although he assumes he has had "more experience" in many forms of disease than many "private practitioners." It is very likely that this may be true as the poor weak fellow has lent himself in turn to every fashionable quackery, and his homœopathy is only the last "hobby." He thus concludes his first lecture: "It is hoped that these explanations will satisfy every enlightened mind that the allopathic mode is like the antipathic, merely a makeshift; that it may beat off the disease, but then it only keeps it off as long as the new action induced by the treatment is powerful enough to arrest the life's action to the new direction; and as in so arresting and so directing the life's action it is exhausting the powers of life, the stock with which each one is endowed, the duty of every well-wisher to himself is to ascertain if there are not means by which diseases may be subdued without such exhaustion. Such means do exist. Homœopathy presents them, but this in the next lecture." He must have a very curious idea of "enlightened minds" if he really supposes he has actually convinced them that the whole science of medicine is "merely a makeshift"—that the cure always exhausts the powers of life; and, above all, that homœopathy is capable of curing "without such exhaustion," or even of curing at all. Dr. Epps, however, affirms that it can, but as is universal among homœopaths, he defers till another opportunity to show wherein consists its superiority, or even to tell us what the new doctrine is. The only alternative for us is to take, as we will now do, the writings of the professors of the new system, and expose the fallacies of their reasonings as they proceed. After reading Dr. Epps's ideas of homœopathy and counteraction, we were very much surprised at the following passage in his work "On Counteraction" previously alluded to:—"It becomes a matter of importance to inquire whether or not there are any means to be adopted so as to create in some part (less essential to life than that in which the disease is), another disease by the creation of which a counteraction is induced, and thus the more important part having the action diverted from it, is enabled, by a little assistance, to recover its healthy condition? Another matter of considerable importance is, whether in cases of hereditary liability to disease we may be able by exciting a counteraction in a part less essential to life, to defend the part by the counteraction thus kept up, from being influenced by any cause tending to excite in the part a diseased action? . . . . . To both these questions the answer is the affirmative. Counteraction is that means, and consequently how extensive must be the remedial principle thereof." Such are Dr. Epps's words on "Counteraction," and we have already seen some of his words on homœopathy. They seem to have a great resemblance to each other, and indeed no one can read the two without seeing that his defence of homœopathy is little more than a paraphrase of his "Counteraction" interlarded with cases in which homœopathy was tried, and a few scattered remarks on globulism. It is but too evident that the Doctor's theories, as well as his practice are continually changing. The different forms of practice he has at different times supported show that his foundations in science are easily overturned, or his scruples of conscience easily quieted, when a more novel, and perhaps more advantageous kind of quackery, is rising in the place of that which has become rather stale; so that we should not be at all surprised to find Dr. Epps forsaking homœopathy and taking a newer idol for his fancy. In the introduction to this work he tells us, "That no two diseased actions affecting the general constitution can go on at the same time in the system;" and adds the weight of his authority to the proverb "Poison kills poison." Now, Dr. Epps gives all this for truth, and yet in this work he says that allopathy (his new name for counteraction), is merely a "makeshift," and can only give temporary relief by warding off the disease as long as the action is kept up. Thus from his own words the

evidence in favour of counteraction is conclusive, and to say more upon the subject would only be to insult the understandings of our readers.

(To be continued.)

## SPECIAL CORRESPONDENCE.

### THE HEALTH OF PARIS.

[FROM OUR SPECIAL CORRESPONDENT.]

PARIS, July 19th.

As the health of Paris is at present a topic of considerable interest, I send you a few details respecting its present sanitary condition, and the weekly death-rate, which you may rely upon as trustworthy, and will I hope interest your readers. According to the official returns the mortality of Paris is less now than it was last summer, but I do not think much of the figures, as many details must be taken into consideration, such as the decrease in the population from the war, the flight of terror-stricken inhabitants, the departure of the Germans and of all resident foreigners, besides the great decrease in the customary number of visitors. Then we have also the large number of prisoners taken and people slain during the reign of the Commune and the subsequent fights. With all these different causes to affect the mortality, it does not seem at all probable that anything like a correct estimate of the mortality per thousand can be formed. We have no accurate idea of the number of population, and the census has been postponed to next year.

It is, however, said that the present state of the city is very satisfactory, the unusual cool weather, up to Friday week last, being no doubt one of the principal causes. Had the weather been as sultry as it generally is here from the middle of May to the middle of July, the consequences might have been different, for numbers of unburied corpses were lying about here and there, and many more very imperfectly buried, having merely a few inches of earth carelessly thrown over them, about which are many idle tales which are not worth repeating here.

The following are the latest returns:—

July 1st— 9th, 803 deaths.  
" 8th—14th, 790 "

There is at this time no epidemic in the city. *La France* gives the rate of mortality per thousand in the chief cities of Europe for the last week, and makes out the mortality in London to be 61, Berlin 47, Naples 34, Vienna 31, Liverpool 29, Brussels 29, and maintains that of Paris to be only 22! What will journals next tell their readers?

We may congratulate ourselves on having an energetic préfet in the person of M. Léon Say, and a most able sanitary commissioner in that of Baron Larrey. Baron Larrey has communicated several times with the Government, and his advice has been, according to many, acted upon in many instances. The hot weather began in good earnest on the 14th, and comes with all the more violence for having delayed so long. It is dangerous to venture out at mid-day, and is even sultry at four and five a.m. This weather tells very severely on regiments ordered to march under it, as many have lately in making a change of divisions between Paris and Versailles. Many of the men sink down on the pavement exhausted. We may hope indeed for a change from this tropical weather to more moderate heat.

## Correspondence.

### WHAT IS FEVER?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—How is James this morning, doctor? I think he will get over it. You are not, perhaps, aware that we held a consultation about an hour ago? No, I am not—did you agree? No, they hold out no hope whatever. Then you do, you say? Yes, I am in hopes he will get over it. May I ask you what you ground your hopes upon? Yes, certainly. The tongue is beginning to clean, that peculiar redness along the edges of it has disappeared and he expressed a wish for something. And upon these you ground your hopes? Yes, I do. Did they agree with you about the nature of the disease? Oh, yes; typhus fever—that is a low form of fever of a typhoid type. What is the meaning of typhus, doctor? But, by-the-bye, they agreed with you about your mode of treatment? did they not? Oh, yes, they said nothing more could have been done. The meaning of the word typhus is “Stupor,” it is a Greek word. Then why don’t you call the disease “stupor fever,” and then it would not sound so very alarming? I cannot tell; it is a form adopted by the Faculty. What is fever, then, can you tell me that? Well, yes. When certain symptoms present themselves, we call that fever. Is a symptom a disease, doctor? No, certainly not. Then how can you call them collectively a disease? I can’t tell; it is a form adopted and accepted by the Faculty. Oh, bother the Faculty; can you tell me where the fever is? It must be somewhere if it is a distinct and substantive disease. I have told you already all about it; when certain symptoms present themselves they form the disease called fever. Yes, but you cannot tell me whereabouts it is; you call it red, yellow, blue, typhus, or stupor, or stupidity fever, or anything else you like, but where is it located? Well, doctor, do you think it is in the brain, lungs, kidneys, or liver? No, certainly not; at least, in my opinion. They are not affected directly, though they may be, and no doubt are sympathetically. Can it be in the muscles, arteries, veins, nerves, bones, or ligaments? No, I don’t think it is. Do you think it would be in the skin, absorbant or exhalant? I cannot think so. What about the stomach and bowels? I think they are deeply concerned. Suppose we remove the heat of the skin. Then the fever vanishes, although it is only a symptom. The disease then must be in the blood, don’t you think so? I believe the blood to be poisoned and have thought so for fifty years. The system receives a shock from a miasmatic poison, more or less violent, and the first symptom afterwards is increased arterial action; then the stomach is out of order, and all the other symptoms instantly follow. I think the poison is of an acid nature and coagulates the blood, deprives it of most of its potash and soda, and thereby destroys in a great degree its serum, leaving little but crassamentum in circulation. Why do you examine the state of the tongue so often? Because it shows us the state of the stomach and bowels. Has it any reference to the brains, lungs, or liver? I rather think not. What keeps up the thirst and dry skin? I cannot tell, unless it is the vitiated state of the blood, it having little or no serum to part with. Then you think the poisoned blood acts particularly upon the stomach and bowels? I do; I cannot see that it acts upon any other part. What, not in the exhalants of the skin? No, they would pour out a fluid fast enough if they have any to pour. Then the tongue and mouth are dry for the same reason, and the stomach secretes little or no gastric juice. Yes; and I think the stomach and bowels are the only parts particularly engaged in this disease, except the blood. The membrane that covers the tongue, does not it line the whole tube throughout? Yes, but it changes its organisation as it descends. In the mouth it secretes saliva, in the stomach, gastric juice, and mucus again further down. You think a restoration of the secretions would be a restoration to health, and that that depends upon the state of the blood? Most undoubtedly. The stomach is the first to give in and we place our whole dependence in it, as with healthy gastric juice we would be in good health; you mentioned your hope of recovery in the appearance of the tongue. What does that depend upon? It must be the result of medicine acting upon the blood; the introduction of oxygen, I think. Then your principle is to act upon the blood? Yes; what else have I to act upon? It is through it I must act upon all parts of the body; the blood is the life of man and when poisoned you see the result; you attempt to destroy the poisonous miasma in the air which produces these diseases,

or rather which poisons the blood. Why not attempt to destroy it in the blood? What is the use of all your medicine, your diuretics, diaphoretics, &c., &c., if they won’t do this? You cannot act upon the skin or kidneys unless through it, and if you do not alter its condition, render it more fluid, in fact destroy the poison in the blood, much upon the same principle you would destroy it in the air, you can be of no service. Throw a solution of the nitrate of potash into a basin containing some of the blood drawn from the arm of a patient, and it will change it at once into arterial looking blood. Might it not have a similar effect if thrown into the system and act upon living blood? It might oxygenise it and destroy the poison. This is just what you do, when you mercurialise the system, a particular poison in the blood attacks the skin and it is called scarlet fever; another attacks the stomach and bowels and is called at first simply fever; when the skin becomes yellow, yellow fever; as the patient gets worse and the blood becomes putrescent, it is then called typhus, putrid, or stupor fever; again, when it attacks the nervous system, it is called intermittent fever or ague; yet in no one case can you point out where the fever is; you are prescribing, for what? The fever. Well, where is it? In ague, the poison remains in the system; but where? There it is at all events until it makes its meditated periodical attack and until it is eventually destroyed by a specific. But we have found no specifics for the other poisons, at least ones admitted by the Faculty. If we can neutralise the poison by mercury, potash, or any such agent, I think it would be a near approach to a specific. What is really the state of the case, in what is called typhoid, or putrid fever? State all the bad symptoms and what do they amount to? Simply that the blood is in a state of putridity and this produces all the fatal symptoms, all of which have arisen from an acid, or acid miasmatic poison in the blood, and the question is, how, and by what means it can be destroyed. The man is dying from “putrid fever.” No, no such thing; for the simple meaning of fever is “heat of skin.” But he is dying from a putrid state of the blood. I have often asked myself the question, could there be animalcula in the poison? The kidneys secrete a fluid which will give you an idea of the state of the blood, in colour, smell and sediment. Yes, I know that, but it will give you an idea of the nature of the poison. Granted; but I have seen people in apparent good health passing a similar fluid, and I have changed it to clear by the introduction of from two to four drachms of the nitrate of potash in twenty-four to thirty-six hours. Admitted; but would it have a similar effect in these cases? “Experientia docet.” I have the highest opinion of that medicine myself; I have used it most extensively and successfully for upwards of forty-five years; but I think it is not much thought of generally, and merely, I presume, because it is such a common article of commerce. There are poisons so virulent that life cannot be saved, they don’t give you time, more particularly in tropical climates, and when the case had been almost prepared for it by this abusing of the system; but where there is time, the introduction of potash into the system, particularly in this form, is of greater moment and interest than it is generally supposed to be, and in my opinion deserves a more extensive trial than I fancy it is thought that it deserves. Although the muriates of potash and soda are found in the serum, I would not like to give the chlorate of potash and although I have often given the potash in other forms, I give preference to the nitrate. Search the “Pharmacopœia” and point out any other medicine more useful; it is very soluble and quickly absorbed, which is very evident from its action on the blood in health, at least where there is little or no constitutional disturbance. Well, doctor, it certainly seems strange that when certain symptoms are clubbed together they produce a disease which you call fever, and yet you cannot point out where the disease is. Is not that a fact? The presence of a hot skin proves most certainly that fever is present; now either the hot skin is the fever, the disease itself or the name fever vanishes. Then you think the disease lies in the stomach and bowels, caused, I presume, by the poisoned blood? Show me where else it is; look at the tongue and follow it down, you can’t make a symptom a disease, do what you will. We have examined, I believe, almost every part of the body, and which has proved the most prominent organ? Is it not the stomach? The poisoned blood is, of course, in every part of the body, but it seems to act upon the alimentary tube more than any other part. However, study, reflect, and think, and try if you can find it any other place, whilst I remain,

Yours truly, ALEX. LANE, M.D., R.A.

## THE TRADE IN FOREIGN DIPLOMAS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having read the letters and communications which appeared for some time past in the pages of the MEDICAL PRESS AND CIRCULAR on this subject, I have arrived at the conclusion that we are making too much of it. How many men are there who enjoy the title of Doctor, also Fellow, by virtues of honorary degrees granted by our own universities and colleges, and where lies the difference. It is surely not so bad for foreign universities to grant honorary degrees to duly qualified medical men practising in these countries, as it is for some lordly archbishop to confer the degree of M.D. on some personal friend, and which degree appears in the Register as a legal qualification. When some of our aristocratic brethren who are entering the profession in such numbers through the new portals get used to their honours, they will be more rational in their views. Yours, &c.,

R. T.

Dublin, July 17th, 1871.

[The sale of diplomas is not capable of being defended, and it, therefore, does not surprise us that R. T. makes so bad an attempt at palliating it. He wants to know "where is the difference" between the grant of an honorary degree to a physician or surgeon of high rank and well tested experience and the sale of a diploma which is not what it professes to be to a man who is not what *he* professes to be. R. T. apparently thinks our readers are fools, and he aggravates the offence by his ignorance of the fact, that ecclesiastical M.D.'s. have ceased to exist for about a score of years.—Ed. M. P. & C.]

## SLOW PULSE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me, through your pages, to place on record a case of remarkably slow, though otherwise healthy pulse, which I have at present under my observation, and which has been steadily at twenty-seven since I first saw the case. The subject is a woman, of about seventy, feeble, and suffering a good deal from flatulency, and otherwise in good health. The heart is rather feeble, but not remarkably so. The intellect very good, eyesight, hearing, &c., all perfect, and no other deviation from the normal standard.

Yours faithfully,

ISAAC ASHE, M.B.

Letterkenny, July, 1871.

## DIFFERENTIAL DIAGNOSIS OF PELVIC HÆMATOCELE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I will feel obliged if you will inform me whether pelvic hæmatocele might be confounded with dysentery or enteritis, and whether it is liable to relapse and prove rapidly fatal when an apparent cure has been effected? Is the tumour always palpable in retro-uterine hæmatocele? Does nausea, obstinate constipation, very scanty secretion of urine, and the feeling of a foreign body in the rectum, sensation of abdominal distension and pain, with little or no tenderness on pressure, and a nearly natural pulse, characterise its early stages?

F. M. L.

[We hardly think that pelvic hæmatocele could be confounded with dysentery or enteritis. Its leading feature is the development of a tumour *suddenly*, behind or in front of the uterus, or in one or other iliac region. From its pressure on the neighbouring viscera it may give rise to irritability of the bladder, and constant but unavailing efforts to defæcate, and may prove rapidly fatal by the sudden pouring out of a quantity of blood into the cavity of the peritoneum. We have not noticed the secretion of urine being diminished, but all the other symptoms enumerated by our correspondent may be present, and, indeed, are characteristic of the affection. We do not remember any case in which a tumour, or at least a swelling, was not detected.—Ed. M. P. & C.]

## CONJOINT EXAMINATIONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the important question of conjoint examinations by the licensing bodies in your number for July 19, 1871, p. 65, I read the following:—

"We observe with surprise that the Council received no information as to the state of the question in Ireland by Mr. Hargrave, the representative of the Irish College of Surgeons."

Before I reply to this most inaccurate statement, and contrary to true facts, I ask, Mr. Editor, who is your reporter of the proceedings of the General Medical Council, for the meeting which terminated Monday, July 10, 1871.

Your obedient servant,

WILLIAM HARGRAVE,

Representative of the Royal College of Surgeons, Ireland, on the General Medical Council.

56 Upper Mount street, Dublin, July 20th, 1871.

[We must decline to reply to Mr. Hargrave's question. We observe, however, that our contemporaries, the *Lancet*, *Medical Times and Gazette*, and *British Medical Journal* corroborate our statement. On the 7th inst., Sir Dominic Corrigan stated that the plan of conjoint examination "could not be carried out in Ireland." Dr. Gull wished to know "why such should be the case." Dr. Quain said that the English colleges "had been straining every point to accomplish 'the task,' and if their brethren in Ireland would undertake the same duty in the same spirit, the result could not be doubtful." It is thus evident that the impression existed that no effort had been made by Irish licensing bodies in the direction of conjoint examination. Nevertheless, Mr. Hargrave, who seconded a resolution immediately afterwards, is not reported in any journal to have said a word to undeceive the Council. On the next day he did state in debate on another motion, that he was astonished at the statement that the arrangement was impossible in Ireland, and it remained for Sir Dominic Corrigan to afford to the Council a coloured statement of the facts. We retain our opinion that it would have been proper that the representative of the Irish College of Surgeons should have repudiated an obstructive policy in his College.—Ed. M. P. & C.]

## Medical News.

Royal College of Physicians of London.—At an extraordinary meeting of the college on Monday, the 24th inst., the following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were granted licences to practise physic, including therein the practice of medicine, surgery, and midwifery:—

Bayley, Robert Luther, M.D., 86 High street, Stourbridge.  
Cottle, Ernest Wyndham, B.A., Oxon., M.R.C.S., Southampton.

Curling, William, 86 Guilford street, Russell square, W.C.

Deepling, George Davidson, Castle terrace, Newark.

Ellis, William Hodgson, M.B., Toronto, Toronto.

Ewart, John Henry, M.R.C.S., Gipsy Hill, S.E.

Goddard, Eugene, M.R.C.S., 27 Pentonville road, N.

Lewis, Lewis, M.R.C.S., 3 Argyll square, W.C.

Lycett, John Allan, M.R.C.S., Middlesex Hospital, W.

Moore, Edward William, M.R.C.S., Grove park, Chiswick, W.

Noakes, Samuel Silverthorne, M.R.C.S., Charing Cross Hospital, W.C.

Parrott, Edward John, M.R.C.S., Buckland, near Tring.

Power, Thomas, 72 Stepmey Green, E.

Ransom, Frederick Parlett, Fisher King's College Hospital, W.C.

Strafford, Thomas, M.R.C.S., Ripley, Derby.

Waller, Walter Augustus Ewen, M.R.C.S., Guy's Hospital, S.E.

Waterhouse, Frederick, M.R.C.S., Pontypridd.

Yarrow, George Eugene, M.D., Heidel, M.R.C.S., 87 Old street, E.C.

The following candidates having passed in medicine and midwifery, will receive the college licence on their obtaining qualifications in surgery recognised by the college:—

Coltart, William Wilson, St. George's Hospital, S.W.

Duke, Douglas Wm., 3 Belvedere place, Upper Norwood, S.E.

**Apothecaries' Hall of London.**—At a Court of Examiners held on the 20th inst., the following gentlemen having passed the necessary examinations, were admitted licentiates of the Society of Apothecaries, viz. :—Messrs. Charles Edmund Aikin, of Clifton place, Sussex Square; Alfred Baldock, of Charterhouse square; Moses George Biggs, of Welford; Francis Charles Bryan, of Delamere crescent, Harrow road; George Haynes Fosbroke, of Bidford, Redditch; Willoughby Furner, of King's road, Brighton; Michael Harris, of Hackney; and George Augustus Tombs, of Cirencester.

**A Murderess of Eleven Persons.**—A sensation has been caused in Connecticut by the arrest at Derby of Mrs. Lydia Sherman, charged with having at intervals during several years past, poisoned three husbands, two step children, and six of her own children; the preliminary examination now going on shows strong evidence of guilt, the bodies of her last husband and a child having been exhumed, and upon examination giving evidence of poisoning with arsenic.

**Society for Relief of Widows and Orphans of Medical Men.**—At a quarterly court of directors held, July 12th, Dr. Burrows, president, in the chair, grants to the amount of £1,278 10s. were made to fifty-five widows, and forty-five children. Two widows and three children were added to the list, the death of one recipient of grants was announced. Two members were elected, and five proposed for election at the next court, to be held in October.

**Alexandra Palace and Muswell Hill Estate Tontine.**—We can only give an outline of a few of the main features, but the details of this new undertaking will be found in our advertising columns. In the first place, no liability is incurred, as it is a trust matter. Every shareholder (or rather Tontineer) has a right-certificate granted him, according him free admission to the palace and its magnificent grounds, and becomes a participator in an Art Union to be established in connection with the undertaking. It is estimated that the funds for disposal towards this Art Union will during the period of the Tontine amount to £500,000; and each 21s. certificate holder may secure five prizes of £500 each. The Tontine is to be closed in 1886, when the property, after having been improved by the devotion of the profits to that end, will be sold, and the proceeds be divided among the Tontineers. Each certificate holder will also provide against loss by a representative life being insured with an office that has undertaken to refund 20s. of every 21s. to each certificate holder. For the various exhibitions and amusements, we must refer our readers to the prospectus.

**NOTICES TO CORRESPONDENTS.**

**PREIDENTIA.**—The insertion of the letter will lead to further discussion on a subject which has had full scope in our columns, and for a renewal of which we have not space.

**Dr. W. Gordon.**—Thanks for drawing our attention to the matter.

**Dr. Bell-Taylor.**—Your communication did not arrive until a portion of the Journal was printed.

**Dr. Alexander Lane.**—Corrected proof not received until Tuesday morning.

The following communications are in type, and will appear, if possible, in our next:

**Dr. Morgan, F.R.C.S.**, "On the Nature of the Venereal Poison, as Illustrated by Direct Experiment and Observation." Illustrated with diagrams printed on toned paper.

**Francis R. Hogg, M.D., M.R.C.S.**, "On Vaccination and Temperance."

**Mr. Teevan**, "On Four Cases of Operation for Unusually Large Calculi."

**Mr. O Flynn, A.M., M.D.**, "On Spontaneous Cure of Vesico-Vaginal Fistula."

**VACANCIES.**

Royal Free Hospital, London. Junior House-Surgeon. Board and residence in the Hospital. (See advt).

Hereford Infirmary. Resident House-Surgeon. Salary £100, with board.

Boroughbridge Friendly Societies. Medical Attendant. Salary £80.

Bournemouth Dispensary. House-Surgeon. Salary £100, with residence.

Hospital for Sick Children. Assistant Physician. Honorary.

Bradford Infirmary. Physician. Honorary.

Bodmin Union. Medical Officer for District No. 2. Salary £31.

**APPOINTMENTS.**

**BROADBENT, W. H., M.D.**, promoted to Physician, St. Mary's Hospital.

**HAYWARD, H. H., M.R.C.S.**, Dental Surgeon to St. Mary's Hospital.

**MARRECO, A. E., M.A., F.C.S.**, Professor of Chemistry at the Newcastle-on-Tyne College of Physical Science in connexion with the University of Durham.

**NUNNELLY, F. B., M.D., M.R.C.P.L.**, an Assistant-Physician to St. Mary's Hospital.

**OWEN, E. B., M.R.C.S.**, Assistant-Surgeon to St. Mary's Hospital.

**PALFREY, J., M.D.**, Physician-Accoucheur to the General Lying-in Hospital, London, vice Alfred Meadows, M.D., resigned.

**PRICE, T., L.K.Q.C.P.L., M.R.C.S.E.**, Assistant Resident House-Surgeon to the East Dispensary, Liverpool.

**REECE, J. R., M.R.C.S.E.**, Consulting Surgeon to the Glamorganshire Infirmary, Cardiff, on resigning as Surgeon.

**SHREN, A., M.D., M.R.C.S.**, a Surgeon to the Glamorgan Infirmary.

**SKEGG, J. J., L.R.C.P.Ed., M.R.C.S.**, Medical Officer of Health for St. Martin-in-the-Fields.

**SWAN, R. J., M.R.C.S.E.**, Medical Officer and Public Vaccinator for the No. 2 District of the Northleach Union, Gloucestershire.

**WILSON, H., F.R.C.S.I.**, Junior Surgeon to St. Mark's Ophthalmic Hospital, Dublin.

**WORKMAN, C. J.**, Ophthalmic Surgeon to the Teignmouth Infirmary.

**SURGEON MAJOR J. FAYRER, M.D., C.S.I.**, Bengal Medical Department, to be Honorary Physician to the Queen, vice C. Mackinnon, M.D., C.B., late Inspector-General of Hospitals, Bengal Medical Department, deceased.

**Marriages.**

**PEPPIN—HERDMAN.**—On the 12th inst., at Walcot Church, Bath, Henry Cole Peppin, Staff Assistant-Surgeon, second son of the late Arthur Bedford Peppin, Surgeon, to Agnes Clara, second daughter of James Herdman, Esq., of Camden crescent, Bath.

**TEEVAN—ROBINSON.**—On the 11th inst., at Christ Church, Kensington, Wm. Frederic Teevan, F.R.C.S.E., to Georgina, daughter of the late Francis Robinson, Esq.

**Deaths.**

**COLLINS.**—On the 13th inst., at Woodhill, Portishead, John H. Collins, F.R.C.S.E., District Surgeon East Indian Railway, aged 54.

**NEILSON.**—On the 15th inst., C. Neilson, L.R.C.S.I., of Killala, Co. Mayo, aged 74.

**MILES.**—On the 16th ult., at Colaba, Bombay, Dr. H. Miles, Surgeon, R.A., aged 58.

**PRITCHETT.**—On the 18th inst., G. W. Pritchett, M.R.C.S.E., of North Hill House, Plymouth, Surgeon R.N., aged 65.

**REYNOLDS.**—On the 10th inst., at Appledore, Devon, William Reynolds, M.R.C.S.E., late of Wellington, Somerset, aged 50.

**Advertisements.**

**THE SIGHT.—SAMUEL'S SPECTACLES** (recommended by the Faculty). Price 2s. 6d. and 5s.  
**SAMUEL'S BRAZILIAN PEBBLES**, price 7s. 6d., Highly beneficial for very weak eyes.  
**FRENCH OPERA GLASSES**, from 5s. 6d. and upwards.  
**RACE, FIELD, and EYE GLASSES** of every description. Can only be had at 29 NASSAU STREET, DUBLIN.  
**CAUTION.**—Beware of imposition. S. SAMUEL has no connection with any one bearing a SIMILAR NAME. The Stock of Watches and Jewellery selling off, declining that branch of the business.

The pure Irish *Frieze Cota Mór* (Travelling Great Coat) WIND AND WEATHER PROOF, manufactured by Kenny and Owens, Merchant Tailors, 54 Dame st., Dublin. The 16s. Trowers House.

**£2 2s. Od.**

**MODERATE IN PRICE. SUITED FOR ALL SEASONS**

These Coats are so well finished, and made of such excellent material, that they cannot fail to please the most fastidious. PATTERNS and FORMS FOR SELF-MEASUREMENT SENT POST FREE ON APPLICATION TO THE SOLE MANUFACTURER, RICHARD ALLEN, 28 L.R. SACKVILLE ST & 52 HIGH ST., DUBLIN; and 69 PATRICK ST., CORK.

**SIR J. MURRAY'S**

**PURE FLUID MAGNESIA**

IS RECOMMENDED BY PHYSICIANS SINCE 1807 for Bile, Acidities, and Indigestion. They also order his **COR-DIAL CAMPHOR** (3 grs. per ounce) as the best restorative for weak nerves or low fevers. His **LEMON'S SYRUP**, mixed with either Fluid, forms a brisk Aperient for any age—bottles 1s. and 2s. 6d. To guard against false liquids the Patentee's labels are subscribed "Sir J. MURRAY, Physician to the Lord Lieut."

MADE IN ALL MATERIALS.

CUT AND FRAMED IN THE BEST STYLE.

**ST. THOMAS'S HOSPITAL MEDICAL and SURGICAL COLLEGE.**—The ACADEMICAL SESSION for 1871 and 1872 will commence on Monday, the 2nd of October, in the new buildings on the Albert Embankment, Westminster bridge, when Mr. F. Le Gros Clark will give the Inaugural Address.

MEDICAL OFFICERS and LECTURERS:—

Honorary Consulting Physicians—Dr. Barker and Dr. Bennett.

|                      |                |                       |
|----------------------|----------------|-----------------------|
| Dr. Peacock          | Mr. Croft      | Mr. Mason             |
| Dr. Bristowe         | Mr. Liebreich  | Mr. Arnott            |
| Dr. Clapton          | Dr. Stone      | Dr. Bernays           |
| Dr. Murchison        | Dr. Ord        | Dr. J. Wale Hicks     |
| Dr. Barnes           | Dr. Harley     | Dr. Wm. Rhys Williams |
| Mr. F. Le Gros Clark | Dr. Payne      | Mr. J. W. Elliott     |
| Mr. Simon            | Dr. Gervis     | Mr. Rainey            |
| Mr. Sydney Jones     | Mr. Mac Cormac | Mr. W. W. Wagstaffe   |

For entrances or prospectuses and for information relating to prizes and all other matters apply to Mr. Whitfield, Medical Secretary, the Manor-house, St. Thomas's Hospital, Newington, Surrey, S. E.

**ROYAL FREE HOSPITAL, GRAYS INN ROAD.**—There is a vacancy for a Junior House-Surgeon at this Hospital. Candidates, who must be members of the Royal College of Surgeons, are requested to send in their testimonials to the Secretary, on or before Thursday, the 27th inst. The appointment will be made for six months only, but the holder will be eligible for re-election. Board and residence are provided in the hospital.

JAMES S. BLYTH, Secretary.

**TAUNTON UNION.**—The Board of Guardians of this Union are desirous of receiving Applications for the Appointment of a MEDICAL OFFICER (duly qualified for the Churehstanton District, comprising the parishes of Churchstanton and Otterford. Area—7,399 acres; population, 1,437; salary, £52.

This salary includes all extra fees of every kind, except 10s. for each case of Midwifery which the Medical Officer shall attend, if lawfully authorised; he will, if duly qualified, be appointed under the Vaccination Act of 1867, with the fees prescribed by the said Act; and he will be entitled to 2s. 6d. per case for each quarterly visit to Lunatic Paupers resident in the district.

Information as to the district, duties, &c., may be had on application to me. Testimonials of Qualification, &c., to be left at my office, on or before Friday, the 20th July, instant. The election will be proceeded with on Thursday, 27th July, instant.

No Candidate need attend unless requested to do so by letter from me.

Residence within the district required.

HENRY CHAS. TRENCHARD, Clerk to the Guardians.

Dated this 13th day of July, 1871.

#### PUBLIC SCHOOL EDUCATION IN IRELAND.

**COLLEGE OF ST. COLUMBIA, RATHFARNHAM, COUNTY DUBLIN.**

VISITOR—THE LORD PRIMATE.

The College is intended for the Education of Boys from the age of nine years and upwards. The Course of Instruction is of the same nature as that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics, English, French, German, Drawing, and Vocal Music.

Boys are prepared for the Universities of Dublin, Oxford, and Cambridge, or for the Military and Civil Service.

Terms for Boarders—Sixty Guineas. A limited number of Sons of Clergymen can be received at Forty Guineas.

There are two Exhibitions attached to the School, tenable at the University of Dublin, value not less than £20 a year.

Lists of the School, and of recent honours gained by former pupils, together with all other particulars, may be had on application to the Rev. ROBERT RICE, M.A., of Christ Church, Oxford, Watling; or at Messrs. HODGES, POSTER, & Co.'s, Publishers to the University, 101 Grafton street, Dublin.

The Summer Vacation ends on August 16.

#### PRIVATE RETREAT

FOR

THE UPPER AND MIDDLE CLASSES

OF BOTH SEXES, MENTALLY AFFLICTED,

TUE BROOK VILLA,

NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWEN. Vide page 1075, "Medical Directory," 1869.

#### MALVERN COLLEGE.

The THIRD TERM will begin on Wednesday, September 20th.

Terms of Tuition and Board, £90 per annum.

For Clergymen's Sons after Examination, £50

Three Scholarships worth £50 per annum for one or for two years to be examined for in December.

For details apply to the Secretary.

#### CHURCH STRETTON PRIVATE ASYLUMS

FOR THE UPPER AND MIDDLE CLASSES OF BOTH SEXES, are situated among the Shropshire Hills, Twelve Miles from Shrewsbury, on the rail to Hereford.

Apply to { Wm. Hyslop Esq., Stretton House, for Gentle- } Church  
men; } Stretton, Shropshire.  
{ Mrs. BAKWELL, the Grove, for Ladies. }

Vide page 1016 in the Medical Directories for 1867.

#### ESTABLISHED 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE  
50 Lincoln's-inn fields, W.C.

**J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c.**, (King's Coll.), and Author of VIA MEDICA, has always upon his books a large number of desirable investments and available Appointments for negotiation. Gentlemen wishing to relinquish practice can be introduced without delay to suitable successors with means at their disposal.

Dr. Langley devotes his prompt personal attention to the negotiations entrusted to him, which are treated with the most scrupulous reserve.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

Dr. Langley can refer to many of the leading Members of the learned Professions in town and country as a guarantee of his integrity and honour in all matters of business entrusted to him.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2.

**LOCUM TENENS.**—Dr. Langley has now organised a thoroughly reliable Staff of Suitable Gentlemen to take full Charge of any Practice which may require it in the absence of the principal, at fees from £2 2s. upwards, according to age, experience, qualifications, &c. One of these Gentlemen can be despatched by an early train after receipt of telegram or letter stating duties and terms. Office fee 10s. 6d. payable by the principal.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on receipt of two stamps) as below:—

**Y 248. UNITED STATES.**—In a large and improving city with a temperate climate and great municipal advantages a PARTNERSHIP with succession for transfer. Receipts average about £2,000 a year. Two valuable appointments to public works are held by the incumbent. Highest references can be given and moderate terms accepted from a doubly qualified British surgeon.

**Y 247. KENT.** In a pleasant little town where there is no qualified opposition an old established PRACTICE realising about £450 a year, with little exertion, appointments yield £150 a year. The residence is a well-built house containing ten rooms with large gardens, meadows, stabling, coach house, &c. Rent £35. Midwifery fees, £1 1s. and upwards. One horse is employed. No assistant required and living very cheap. A complete introduction can be given to a suitable gentleman; time would be allowed for payment of part of the premium.

**Y 246. LONDON.** Cash practice of £1,200 a year. An active PARTNER is required with £80 at his command. The books are open to the most rigid scrutiny and a personal experience of the practice can be allowed under suitable conditions. There are no bad debts. The principal attends no midwifery under £1 1s. The incoming partner may rely upon a clear income of £500 a year after payment of all expenses.

**Y 245. LONDON SUBURBS, S. E.** In a pleasant district, a good NUCLEUS for TRANSFER, affording an introduction to a few respectable families. Receipts £120 a year. Convenient house in a rapidly increasing district. Rent £30. Premium £100 to include valuable fixtures, surgery, &c.

**Y 232. LONDON.**—A large and old established PRACTICE for Transfer, under conditions affording the highest guarantees of good faith, as the vendor is retiring in consequence of serious and sudden illness. The books show that upwards of £435 were taken in ready money fees during last year, and that more than £700 were booked; the previous years show a much higher average, and very few bad debts. Midwifery fees at £1 1s. and upwards, yielded £140. Public appointment £350 a year. The residence is extremely convenient, situated in a principal thoroughfare, with garden at the back, and stabling. Rent £80 a year. There is a detached Surgery, where the Assistant resides. The introduction to the Practice may be by Partnership or otherwise.

**Y 243.** In a large COUNTY TOWN, within easy access of London. Established 40 years, and owing to peculiar circumstances more than usually transferable. The receipts for many years past have been upwards of £800 a year. The returns during the last six months have been at the rate of £700 a year, exclusive of appointments, which realise about £50 a year. The vendor retires upon the advice of a London physician, to whom reference can be made. Visiting fees are 2s. 6d. and 3s. 6d. without medicine, in addition to mileage. A qualified assistant, who has been for many years engaged in the practice but prohibited from acting on his own account, can be retained if desired. The house is large and commodious, with large garden and detached stabling. The whole with a rental of £55. There is a local hospital, and the population of the town and district is upwards of 30,000. Excellent field sports in the vicinity. The parish appointment will shortly be vacant, and could be claimed by the successor.

**Y 242. LONDON, West Central District.** Receipts nearly £500 a year, capable of almost unlimited increase. The practice is wholly private, except appointments connected with the theatres. Rent £75 a year. The successor need not be married, and the practice can be conducted without assistant or carriage. An efficient introduction can be given.

**Y 240.** In a pleasant London suburb, surrounded by a rapidly improving district of villa residences, a small but increasing FAMILY PRACTICE for TRANSFER. In consequence of the delicate health of the vendor the practice has not been actively pushed, and the receipts have amounted to about £400 a year; appointments, £50; no low midwifery. The practice can be conducted without a horse or carriage. Patients of a good class. The house is conveniently situated; rent £60 a year. The fullest investigation courted.

Dr. Langley's Quarterly List of Selecting PRACTICES and PARTNERSHIPS for JULY is now ready. Post Free on application.]

## Original Communications.

### ON THE NATURE OF THE VENEREAL POISON AS ILLUSTRATED BY DIRECT EXPERIMENT AND OBSERVATION.

By DR. MORGAN, F.R.C.S.I., M.D., Univ. Dub.

Surgeon to Mercer's, and to the Westmoreland Lock Hospitals, Dublin; Professor of Surgical and Descriptive Anatomy; R.C.S.I. &c.

IN THE MEDICAL PRESS for July 12, 1871, I have shown from Mr. Wallace's note books that the formation of the characteristic pustule and ulcer of the soft non-incubative type was followed by constitutional signs. These sores were produced on *healthy* subjects, and, as in the cases I quoted, derived from Richard Bradshaw (a patient suffering from secondary ulcerations), were undoubtedly derivatives of true syphilis; but as modified by descent, and produced from constitutional evidences, the primary appearance was that of the characteristic pustule and soft or chancreoid ulcer. Indeed, if direct experiment be of any value whatever, we must be satisfied that the result of inoculation from "secondary ulcers," from suppurating bubo, and from a "superficial phagedænic sore"—however unwarrantable they were when practised on sound persons—has been shown by Mr. Wallace to be the characteristic chancreoid, soft, or simple sore. The history I have quoted of inoculations from R. Bradshaw's secondary ulcer, and the unequivocal and plainly described cases given by Mr. Wallace, in the *Lancet* for July 22, 1837, p. 617 and 618, where inoculation was performed from a suppurating bubo on a *healthy* subject, and was nevertheless followed by constitutional signs, prove the fallibility of the dual theory, and especially the existence of a constitutionally infecting poison whose introduction is manifested by a sore not necessarily preceded by an incubative period.

Mr. Wallace's direct experiment is so striking that I cannot forbear giving an outline of it. He says:—

"March 3, 1825.—I made three punctures on the thigh

of a *healthy* man, aged twenty-five, and applied to them matter discharged at the moment of opening a bubo, which existed in a person who had several well marked primary pustular ulcers on his penis (a most satisfactory history of the chancreoid lesions).

"March 5.—Each of the punctures has inflamed.

"March 6.—Centre has black point, surrounded by a yellow line, &c., and the usual history of the chancreoid inoculation is given.

"May 8.—Soreness of throat and inflammation of isthmus faucis.

"May 10.—Pain and swelling of upper bone of sternum, and eruption of about twenty pustules on his face and arms.

"May 13.—Complains very much of pains in his breast, forearm, elbow and ankle; most severe at night."

If this direct experiment be put in juxtaposition with those I have last given of Philip Wall (Case No. 2), infected from a secondary ulcer; or of J. F. and John T. (Cases 3 and 4); the phenomena of all are similar: yet who can doubt the existence of constitutional taint following the local manifestations of their chancreoid sore. I am by no means surprised at these results as I have seen unquestionably as severe if not severer, constitutional signs follow the chancreoid sore, than the sore ordinarily recognised as the infecting or chance proper, in men not unusually and in women frequently. I have before stated that "nearly all the patients in the Dublin Lock Hospital suffered from this form of sore;" the other surgeon, Mr. McDowell, stating that it is "generally, certainly not always, the most frequent form of sore." Yet constitutional signs are almost invariable. Various ingenious adaptations and distortions of popular theories have been attempted, so as to avoid or explain away this everyday experience, but which I have before alluded to and dissipated.\* The fact remains incontrovertible. Indeed, the following instance given by Boeck in his straightforward and unbiassed manner is conclusive, and is quite in conformity with usual observation here. He says p. 64:—

\* MEDICAL PRESS, March 22, 1871, p. 239.

"A very young girl, K. E. (whose sister was a *fille publique*), intending to adopt this kind of life, presented herself for inspection, and received the usual certificate from Mr. Lund, the official surgeon, who noted at the same time that *she had the hymen intact*, and was therefore a virgin. In a few days afterwards she came to hospital suffering from small non-indurated ulcers near the vulvo-vaginal glands. She was frequently examined with the greatest care, but no other affection could be found; but in six weeks afterwards constitutional signs appeared. Any inexactitude of examination must be regarded as impossible in this case, and this observation, together with others, has made me certain that the non-indurated chancre in women can produce constitutional syphilis."

Can anything be more conclusive, and yet such instances as this resemble exactly what is seen in Dublin, where young girls constantly present the usual phenomena of soft sores; they have been tested by auto-inoculation, suppurating bubos occasionally accompany them, yet constitutional signs follow.

Mr. Wallace's inoculations in men above alluded to are equally illustrative. Several cases are given, some of which I hope to tabulate, on account of the invaluable information, as no author practised on the principles that he did of indiscriminate experiment. It must be admitted that he did not then discern clearly as to gonorrhœa not being syphilitic, and he performed subsequently a series of experiments to determine the question.

I have selected one remarkable instance from his notes which bears on the question lately raised by Dr. Hammond; New York ("Lectures on Venereal Disease," 1864, p. 255), where he states that the introduction of the chancroid virus, or indeed of the chancre proper, into the urethra will produce a gonorrhœa; and he illustrates the result by experiment. On examining the result of the direct action of the virus of the "superficial phagedænic sore" of T. Gavan, as indicated in the accompanying illustration, we are struck by the varying effect:—The production of a hard sore in his wife, which assumed after a time a phagedænic edge; the production of a gonorrhœa in M' Connor (Case 7), and in P. Phillips, aged sixty, who had not had gonorrhœa for years, yet is noted as having discharge forty-seven days after the introduction of the matter from Durham's sore, while in others it failed; and in W. Garvey (Case 6), it is particularly noticed no discharge was produced, although the lint soaked with the virus was left in three hours; while in P. Keegan (Case 9), the phenomena produced by inoculation were those of the chancroid sore; but as Gavan himself suffered from intense constitutional signs, it can hardly be supposed that Garvey was not infected.

I have collected the histories of the cases as far as the reports extend, and intend this series to illustrate the effect of the superficial phagedænic sore, as so named by Mr. Wallace, when tested by experiment.

*Experiments from a Superficial Phagedænic Sore.—  
History of the source of the infection used.*

December 28.—J. Gavan has phimosis and superficial ulceration of the upper part of the orifice of urethra; rather healthy looking; the body of the penis feels hard and swelled; the whole of the right side of the penis from the pubis to within an inch of the orifice of the urethra ulcerated; it is superficial, its surface is pulpy, whitish, in some parts at the circumference is pustular pulpy white; the surface is rather raised over the surrounding skin, the edge is abrupt. There is another ulcer at the left side of the penis of the same character, one inch long and half an inch broad; the skin lies loose on a large portion of the orifice of the penis, which is not ulcerated, and when removed the cutis underneath is whitish and pulpy, and on scraping it bleeds. The skin of the scrotum, particularly at root of penis, is red and swollen. About two months ago got two pimples—white, like pins' heads—level with the skin on the corona, fol-

lowed by phimosis. About six weeks ago an appearance came on the outer skin as if it had been scalded red; this formed the present external ulcers. The orifice of the prepuce is so much contracted that he is hard set to make water.

January 4.—The sore is redder; inoculated spots have formed pustules with areolæ and black crusts (the site of the inoculations is not mentioned, but it was evidently between the 28th December and 4th of January).

January 11.—The inoculated spots have the common character, &c.

January 21.—The punctures healing; the sore looks redder; where caustic had been applied is healing. His throat is red, swollen, painful, hoarseness, and eruption on shoulders, hips and back; and finally slough of pharynx and iritis, secondary ulcers, &c.

*Case No. 1.*

January 29.—James Bolger (Fig. 1), has a white sloughing chancre of five weeks' standing, which destroyed frenum, with considerable hardness of prepuce; have cut left thigh with J. Gavan and right with his own, and also above this with J. Gavan.

January 30.—No inflammation.

February 5.—None of the punctures have inflamed; there was a tumour rapidly advancing in his left groin. (No further history; it may be concluded there was no effect.)

*Case No. 2.*

January 29.—L. Kavanagh (Fig. 2), removed warts from inner surface of prepuce with scissors, and cut him on left side of inner prepuce with J. Gavan.

February 8.—The puncture has not inflamed, the warts seem growing again.

February 21.—Inoculations failed, warts growing; cut with Gavan on right, and Durham (suffering from intense constitutional signs and secondary ulcer of right leg which furnished the matter) on left thigh.

February 24.—The punctures a little inflamed.

February 25.—The punctures have not inflamed any more; passed matter of Durham and of Keating (with an elongated ulcer on prepuce, nearly in its granulating stage) into his urethra with lint.—No further history, and it may be concluded there was no effect.

*Case No. 3.*

February 1.—T. Allen (Fig. 3), aged twenty-four, has gonorrhœa a month. Cut with matter of J. Gavan.

February 3.—Punctures on thigh are a little red. He seems to have scabies and lepra vulgaris. The orifice of the urethra was also scarified, without any effect.

February 5.—The punctures have not inflamed; the orifice of the urethra remains free from sores.

No further history; all probably failed.

*Case No. 4.*

January 29.—P. Reilly (Fig. 4), gonorrhœa a few days; cut left thigh with J. Gavan.

February 1.—No inflammation of the punctures. No further history.

*Case No. 5.*

February 1.—M. Byrn (Fig 5), external and internal gonorrhœa, cut with matter of J. Gavan on left thigh.

February 3.—The punctures not inflamed.

February 12.—Has somewhat the appearance of a raised primary sore disappearing on his inner prepuce. No inflammation of the punctures. Now cut on right thigh with J. Gavan.

February 21.—The cuts on right thigh look scurfy, but not inflamed. Cut lower down with J. Gavan, by lint laid on.

February 25.—Inflammation of punctures disappeared. Cut again with J. Gavan.

No further history; it may be concluded there was no further effect.

*Case No. 6.*

February 19.—N. Garvey (Fig 6), a patient suffering from a sore and ulcerated bubo. The matter of J. Gavan

ON THE NATURE OF THE VENEREAL POISON.

BY MR. MORGAN, F.R.C.S.I., &c.

*Illustrated by Mr. Wallace's Inoculations.*

EFFECTS OF INOCULATION WITH THE SUPERFICIAL PHAGEDENIC SORE

Of J. Gavan, who presented himself Dec. 28. On Jan. 4 the inoculations on his thigh had produced "pustules with areola, and black crusts," on himself. On Feb. 21 inoculation from his sore succeeds with Fig. 9, and fails with Fig. 5. On Feb. 19, when mixed with the patient's own discharge, produces gonorrhoea, by being passed into the urethra.

Fig. 12.—M. Gavan, the wife of J. Gavan, suffered from a sore with a hard base on the labium, which assumed a phagedenic border, followed, in due time, by constitutional signs.

Fig. 1.—J. Bolger. Both his own and Gavan's discharge failed when inoculated.

Fig. 4.—P. Reilly—  
inoculation failed.

Fig. 5.—M. Byrne—  
repeated inoculations failed.

Fig. 8.—J. Walsh—  
matter from his own sore and from Gavan mixed, and passed into urethra; probably failed.

Fig. 11.—J. Craven—the matter of Durham, + and of Gavan both failed to inoculate.

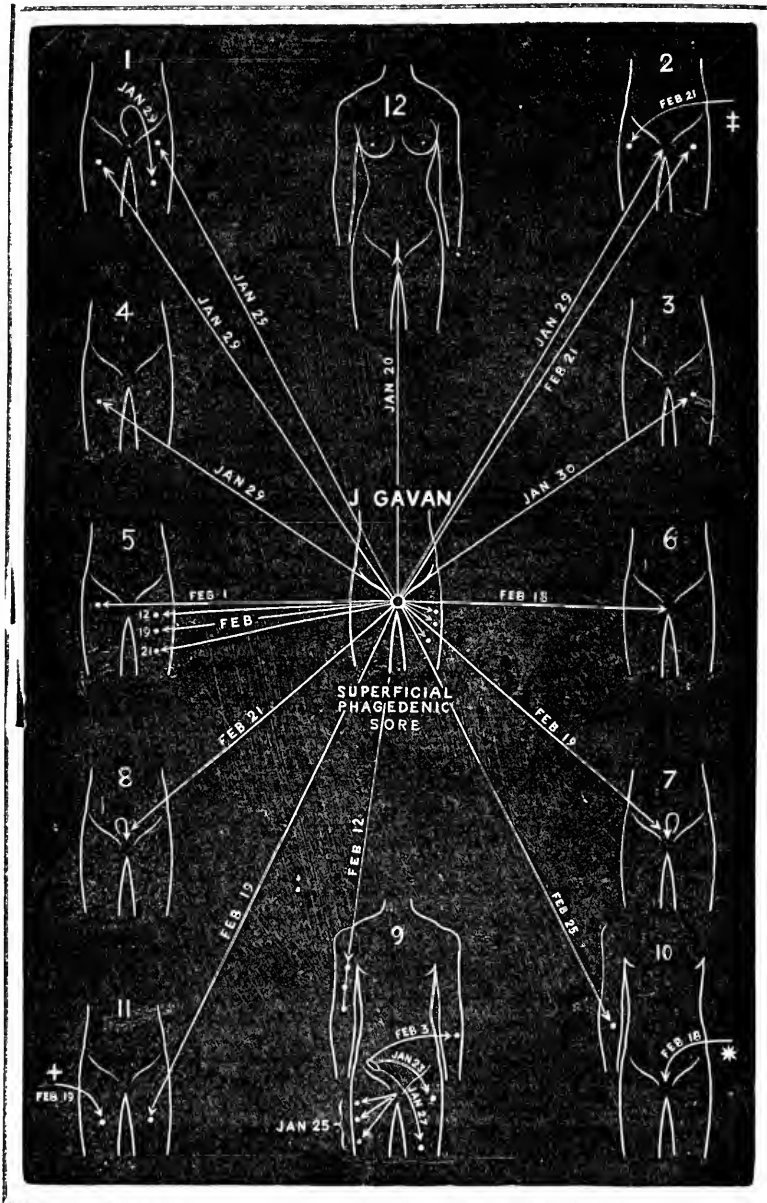

Fig. 2.—L. Cavanagh. Gavan's inoculations failed; Durham's; inoculation also failed.

Fig. 3.—J. Allen—  
inoculation failed.

Fig. 6.—N. Garvey. Sore of Gavan and his own bubo discharge were inert when introduced into the urethra.

Fig. 7.—M. Connor—the discharge of his own sore, and of J. Gavan's, when introduced into the urethra, succeeded in producing a discharge.

Fig. 10.—P. Phillips—the matter of Durham's\* sore, when introduced into the urethra, produced a discharge. The matter from Gavan failed to inoculate.

Fig. 9.—Pat Keegan. See Case 9, which is remarkable. (1) He resisted inoculation from gonorrhoea with indurated urethra; (2) he resisted inoculation from a child's secondary ulcer; (3) he resisted inoculation from his own suppurating bubo; (4) he resisted inoculation from his bubo when healing; and, finally, he is inoculated from the sore of J. Gavan, on Feb. 12, which had failed on the same day with M. Byrne, Fig. 5, and at various other dates, with the several others.

passed into the urethra (matter from his own bubo had been passed into urethra without effect January 27). No effect was produced on the urethra; the lint remained in for three hours, &c.

February 24.—Says his urine has some difficulty in getting out of the passage. I see no difference in his state, &c.

March 9.—A copious rash, &c., appeared.

April 20.—Is full of pains, &c.

*Case No. 7.*

February 21.—M. Connor (Fig 7), primary sore on inner side of prepuce, rather superficial, and ulcerated bubo in left groin. I have passed lint from Gavan's penis and dipped in Connor's own matter into his urethra. He says there is some discharge from his urethra, but no ardor.

February 24.—Says there is much more discharge from his urethra since the day after that on which the matter was passed into it. End of report.

*Case No. 8.*

February 21.—Thomas Walsh (Fig. 8), sores rather superficial, but characteristic on the surface of the prepuce; has erections with tightness of prepuce; have mixed matter of Gavan and his own and passed into urethra.

No further history; it may be concluded there was no effect.

*Case No. 9.*

(Described by Mr. Wallace as "gonorrhœa with bubo.")

January 15, 1835.—P. Keegan, æt. sixteen, gonorrhœa with indurated urethra and lump in left groin of four months' standing. No pain in urinating. Inoculated his left thigh in three places.

January 20.—Inoculated from the matter of an infant who had secondary sores.

January 23.—The spots have not inflamed. This case was a chronic catarrh with a small bubo in the left groin which is red and desquamating. I have allowed the matter to escape, and with it have inoculated right thigh.

January 25.—The spots have not inflamed; the sore in the groin has projecting lips.

January 27.—The thigh has not inflamed. I have inoculated him from the matter of the bubo as now secreted.

February 3.—Cut the right fore arm with matter from the groin; the other punctures have not inflamed; the groin seems healing.

February 5.—The punctures on his arm have not inflamed.

February 12.—Cut on left forearm with Gavan, and desired not to return unless punctures inflamed.

February 14.—The boy attended in consequence of two of the punctures in his left forearm having inflamed. They have a tumid red appearance.

February 17.—The cuticle removed to the extent of a split pea or more; it seems loose at the edge as if it was detached from a vesicle. The surface itself is red and rather raised; the base feels tumid.

February 19.—The spots have extended in a bullous or vesicular manner, but not in depth. The surface exposed is red, and is like the surface exposed in the small and superficial pustular form, or has somewhat the appearance of a condylomatous surface.

February 21.—The spots on his arm are become drier and less inflamed, and are covered with a yellow crust. The groin is healed and the urethra better.

February 24.—One of the punctures seems still more red, a portion of the crust removed from the other, and the denuded surface looks fungous.

There seems no further history. Like many dispensary cases the patient probably ceased to attend.

This patient suffering from a late suppurating bubo and gonorrhœa with which Mr. Wallace calls indurated urethra, a term he frequently seems to apply to the condition in acute gonorrhœa, resists first inoculation with

his own discharge, therefore there was no larval chancre; secondly, the matter from constitutional sores of an infant; thirdly, the matter from his own bubo directly when it was opened; fourthly, the matter from the same after some days; fifthly, the matter from the same when healing; and finally, when inoculated from a patient suffering from "superficial phagedænic" ulcer produces characteristic pustular sores.

*Case No. 10.*

February 16.—P. Phillips (Fig 10), æt. sixty the subject of prurigo, has formerly had gonorrhœa; no discharge now, or for years. Passed the matter of Durham (also used with L. Cavanagh—Case 2), into his urethra.

February 21.—No discharge from urethra; passed Durham's in again.

February 25.—There seems to be some discharge from the urethra; cut on arm with matter from J. Gavan.

April 13.—Has still a discharge from the urethra.

*Case No. 11.*

February 19.—J. Craven (Fig. 11), has had gonorrhœa and chordee for some time. Scarified his thighs and applied Durham (see Case No. 2), to right and Gavan to left.

February 23.—The spots have not inflamed.

*Case No. 12.*

February 3.—M. Gavan (Fig. 12), æt. twenty-eight, the wife of J. Gavan, has a diseased spot on lower part of the left labium, covered with a brown crust, and has a very hard base; says it commenced about a fortnight ago as an itchy pimple; says her husband was disordered for nearly two months when she came to him.

February 12.—Ulcer the same; very deep and hard base.

April 15.—Ulcerated throat, looking badly, deafness, pains in shoulder; the diseased patch on the pudendum has become an excavated ulcer with rather a phagedænic border.

May 23.—Superficial ulcer of palate, two tubercular spots on the chin, and pains.

September 10.—Pains, hemicrania, sore angle of mouth, scaly tubercular rash, three or four subcutaneous tubercles (gummata), and night sweats. Sore is healed.

I have given the notes rather copiously, so that each reader may judge for himself, as to these remarkable facts, that a sore which is auto-inoculable on the patient's self, on January 4, produced a successful inoculation (February 14), on Case No. 9, but fails in other cases; and when introduced into the urethra of Case No. 6 produces, in combination with the patient's own discharge, a gonorrhœa.

### SPONTANEOUS CURE OF VESICO-VAGINAL FISTULA.

By D. B. O'FLYNN, A.M., M.D.

Mrs. D., æt. twenty-seven, in her first confinement had a tedious labour, and was ill from Saturday night until the following Tuesday. She was a person of robust health, but of small stature, and suffered much from the severity of her pains; towards the close of the labour the midwife made forcible efforts to bring away the child. At this time I was summoned to see her, and when I arrived at the bed-side I found the child dead, the funis torn, and the perineum ruptured. I removed the placenta without any trouble, and she expressed herself greatly relieved, as she had suffered much from cramp during the last six hours. She lost all control over the lower extremities, and was unable to move in bed without assistance. At the end of four days a slough came away, and I discovered a large vesico-vaginal fistula, through which the urine passed freely. The fistula was situated far back in the vagina, running transversely, and there was great loss of substance. A fortnight after her confinement she was examined by Dr. Nathaniel Hobart, of Cork, who consulted his uncle, Dr. Hobart, who has been a most successful operator in such cases; those gentlemen agreed to defer operating for three months, until the parts became firm enough to hold sutures. As the woman was

not able to walk or even stand, she had to remain in bed almost immovable. The treatment consisted in washing the parts with tepid water, and applying a lead lotion. At the end of two months the fistula was healed, and she could retain her urine the usual time. In another month she was able to walk with the aid of a stick, and now, at the end of five months, she is quite recovered, and says "she feels all right." Dr. Hobart remarked to me when he saw the case that spontaneous cure was more likely to take place in a large than in a small fistula. On this point I can give no opinion myself, but I believe it is rare to effect a cure in any way after sloughing, and I am inclined to attribute the result in this case to the fact that the woman was kept the whole time in bed, and the mobility of the parts prevented, so that the *vis medicatrix nature* was not interfered with.

### VACCINATION AND TEMPERANCE.

By FRANCIS R. HOGG, M.D. St. And., M.R.C.S.E.  
Royal Horse Artillery.

PRIVATE MURPHY MAGUIRE, with a pair of black eyes and a tremulous appearance, attributed to falling over a bed-iron and feeling nervous before an officer, is a gentleman not above patronizing the slums occasionally. Like the nobleman at Madame Rachel's, possibly his motives spring from the idlest curiosity, or a desire to study human nature under various phases. Abroad also soldiers are exposed to virulent small-pox—in Japan, Bengal, and other places, yet only one in a thousand is attacked, and less than one in ten thousand dies. This comparative immunity, considerably influenced by the rigid performance of vaccination and re-vaccination by the Army Medical Department, still riding favourite hobbies, raising doubts, and damning with faint praise Jenner's supreme discovery. Medical men are found in the ranks of the anti-vaccinators even in this age of progress.

After many years extensive experience, the most perfect specimen of vaccination recently came under my notice. The mother, a fresh complexioned healthy lady, æt. twenty-seven, born and resident twenty-five years in some of the most pestilential parts of India, there suffering from varicella, rheumatic fever, cholera, ague, and measles, in the eighth month of pregnancy she gave birth to six children, four of whom survived. Even in sickness and nursing she has always been a water drinker, and her rosy cheerful face would lead one to imagine that Scotland instead of Peshawar had been her habitation. Her husband, also a water drinker, found alcohol most valuable temporarily when suffering from liver disease.

### CONCLUDING HINTS HOW TO MAKE VACCINATION MORE EFFICACIOUS.

[With Woodcut of a Vaccination Sleeve.]

By R. HANSLIP SERS, M.R.C.S.E., Epperstone, Notts.

BESIDES the condition of the child's skin and bowels, the state also of the *mouth* and *throat* should be ascertained. Congestion, aphthæ, ulceration may apprise us early of approaching disease. When a few papulæ are observed upon the skin, it is well to prepare the parent for a further development of the eruption, or the question, "Is the matter good?" may be followed by the demand, "Was the matter good?" I have stated that I have found two months and a fortnight the most suitable age at which to vaccinate. My reasons for this belief are as follows:—Before this period, the infant is too tender, save under urgent pressure to operate upon; afterwards, dentition may commence to produce its manifold disturbances. Muscular action becomes more marked and vigorous, and practice teaches us that any inflammatory action of the arm less rapidly subsides. I have known vaccination to apparently fail from drying up of the abrasions where from a trifling cause, there has been a slight delay in the subsequent application of the

virus, but still more commonly from *inferior quality*, or *insufficient quantity* of store lymph. Also in discharging the contents of a capillary tube, the operator must be careful to prevent the entrance of his own saliva (the lips should be dry), and if this incident occurs, not to mistake it for a liberal supply of lymph. In charging the capillary tube, it may be possible in a moment of comparative carelessness to appropriate the dribbling from the child's mouth, in lieu of lymph. Our capillary tubes admit of improvement they ought to be now uniform in size, and less jaggy in their terminal outlines. When the slight abrasion necessary for vaccinia is followed by undue flow of blood deficient in colouring matter, and I have noticed this in syphilitic children, I should suspect a taint, and avoid the child as a vaccinifer.

Outsiders require the assurance that vaccination is not an inoculation of scrofula, syphilis, cancer, or malignant disease—that vaccine-lymph is simply cow-pock virus, certainly not a mystic fluid capable of evolving every ill to which flesh is heir—nor need they feel alarmed about any mythic "infinitesimal dangers." The terrible epidemic of variola still raging in our great metropolis, has led to an unusual demand of vaccine-lymph, and one may be excused for an expression of curiosity relative to the source from whence the matter has been and continues to be obtained. Even in rural districts, where purer air does much towards counteracting the defects caused in too many cases by unsuitable marriages, wrong course of life, intoxication and its attendant vices, one feels it difficult to keep up a series of healthy arms, so as to command a good supply of the genuine virus. When one considers the amount of disease among infants in large towns, and the dead loss of store lymph in cases of re-vaccination, it is marvellous how the difficulty is overcome. The pressure arising from the urgent want of lymph, is apt to tell severely upon those from whom it is obtained. Yet the caution is not unneeded to avoid draining puncture vesicles, or the recommendation to leave one vesicle untouched. In cases of emergency where we are obliged to *exhaust* an only vesicle, it is, I believe, the safer and better course to re-operate upon the little patient, in order to insure an extra vesicle. There is another consideration probably brought forward in a recent number of this Journal, which makes this plan advisable—viz.: a plurality of cicatrices yields satisfactory evidence of additional security from contagion.

As it is not unlikely that the public may be supplied with plain directions about vaccination, so in this place, it may be remarked that vaccinia, like dentition, may have harmless irregularities. To give an example, a scab may precede the *full* development of a vesicle. This is not infrequent, particularly when the vesicle is *very large*. The vesicle becomes, as it were, after a variable period, *circumfluent*. Hence, the form of the cicatrix may alter with the depth, extent, and shape of enticle, scratched, or scraped off. The central portion in the illustration before us, *prematurely* scabs, and in due time leaves a perfectly white and *smooth* surface; whereas the circumference is deeply pitted, showing where more prolonged and specific inflammation has extended. The accidental removal of the highly contagious scab, especially when foreign bodies are present, may lead to troublesome ulceration, and the hardened edges thereof may simulate chancre. The after appearance of a cicatrix must be more or less modified by the *nature* of the skin. Moreover, the inflammation around the vesicles may produce vesication, and even bullæ without detriment to the patient. A cell or two of a vesicle, may fill with blood, and the contents may become either serous or sero purulent.

Although it is not in our power to determine with precision, the ultimate size of a vesicle, yet it must be borne in mind that our mode of vaccination must chiefly influence its future dimensions. In an endeavour to make a vesicle to equal two or three vesicles, we are apt to far exceed the mark, hence it is in my opinion the safer plan to produce a small vesicle at the commence-

ment, and even with this precaution, the subsequent extension may be more than is desirable. In an instance which lately came under my notice, the upper vesicle measured three quarters of an inch in length, and the lower just half an inch. Heroic vaccination is not popular.

Armed with a vaccination sleeve I confidently look forward to a more regular course of the vaccine vesicle, to an increased supply of genuine virus and a greater control over casualties. The immense benefit to be derived from the removal of all sources of pressure will, I contend, admit of the strictest demonstration. Through the active co-operation of Mr. Miller, Leicester square, London, I have succeeded in obtaining a vaccination sleeve simple in construction, and easily applied. It is hung around the neck and may be further fastened if deemed expedient either to the attachment encircling the child's neck or to its dress. The latter directions will scarcely have to be followed if the vaccine vesicles be placed a little below the insertion of the deltoid muscle. The sleeve tilts somewhat forward, and it is necessary to arrange the vesicles as far from its upper margin as convenient. The apparatus loosely surrounds the arm and cannot, I trust, by any chance, impede the circulation or prove in itself a source of irritation. Among the poorer class it may be passed after due immersion in a weak solution of Condy's fluid, &c., from one child to another.

The Illustration represents a full-sized sleeve for an infant *et. ten weeks*.

#### DIRECTIONS HOW TO APPLY THE VACCINATION SLEEVE.

1. It should *always* be placed around the neck and arm prior to vaccination.
2. It must be suspended from the proper loop-hole.
3. Draw a chalk crayon along the side rim of the concave front—apply the sleeve *flattened* to the arm by which means is obtained an exact outline of the space within which to vaccinate.
4. Slightly *bend* or *expand* the zinc arch in order that it may correspond with the inner and outer edges of the arm without exerting pressure on either side.

5. Immediately after vaccination the sleeve may be buttoned, very thin children excepted, through the *first* slit in the waterproof cloth.

6. The mother having redressed the child can tie up the sleeves with the front tapes.

N.B.—The zinc arch must stand forth in as bold relief upon the arm after complete fixture as it previously did (otherwise the sleeve is not a fit one for the child), and the mother can be directed to watch that it retain its shape—a slight lateral pressure made with the forefinger and thumb will effect this object if needed.

However, increased experience may lead me to dispense with Regulation 6, as the sleeve should follow every action of the arm. The button, &c., may be superseded by a more convenient outside contrivance.

Is it not time that the custom of permitting the specific inflammatory arm of a tender infant to be open to every passing accident should be abolished? Modern surgeons rarely

hold with a similar exposure of any other species of ulcer, wound, or inflammation.

#### MILLER'S DESCRIPTION OF THE VACCINATION SLEEVE.

(Child *et. two months and two weeks*).

The materials employed in its construction are perforated zinc, waterproof cloth, and tape. When complete it may be briefly described as follows:—

A perforated shield formed somewhat in the shape of an arch passes round two-thirds of the arm, as shown in the diagram, the remaining third being encircled by a broad strap made of waterproof cloth. To the upper part of the shield is attached a series of tapes, two of which are for fastening to the dress whilst the third and longest one is destined to pass over the shoulder and form a loop which fastens round the neck. The dimensions, of course, vary according to the symmetry of the child's arm, but the length for a child of ten weeks is  $1\frac{1}{4}$  inches measuring from the lower margin of the axilla midway to the elbow. The breadth, however, need not be taken into consideration, for zinc being of a pliable nature the shield can be made to accommodate any sized arm. Finally, the straps are made with graduated button-holes, so that the sleeve cannot fail to fit any child of a similar age.

#### NOTES UPON THE EPIDEMIC OF YELLOW FEVER IN BUENOS AYRES OCCURRING IN THE EARLY PART OF PRESENT YEAR.

Reported by JOHN W. MARTIN, M.D.

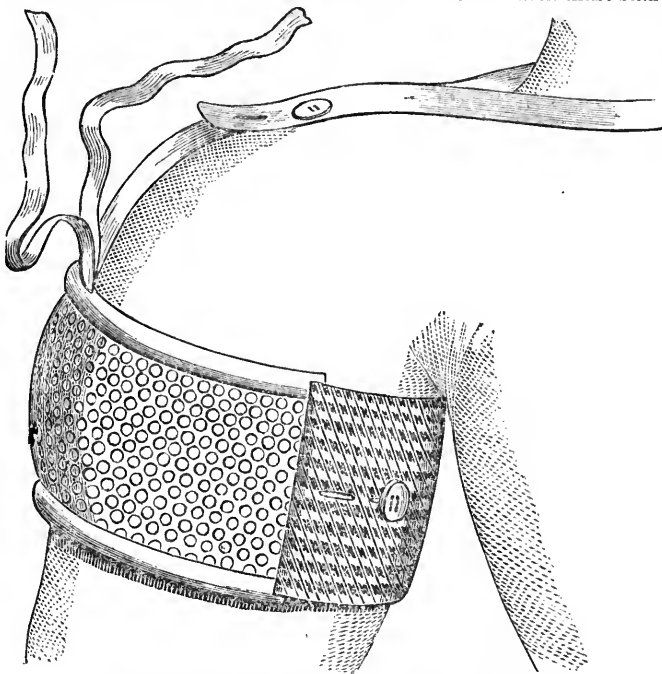

Assistant Surgeon to the Mayfield Factory Dispensary; Ex-Assistant Surgeon to the North Tipperary Light Infantry Regiment of Malitia, &c., &c.

HAVING just returned from Buenos Ayres, it may not prove uninteresting to the readers of the MEDICAL PRESS AND CIRCULAR, that I should put together briefly what

information I was enabled to gather, during the short stay of the S.S. *Copernicus*, on board of which vessel I held the post of Surgeon, relating to the terrible plague that raged in that city, for a period, commencing in the latter part of January, extending through February, March, April, and into the early part of May.

A minute description of the town would occupy more time and space than is requisite; but I must endeavour as shortly as possible, to describe its leading features.

Standing at but a very slight elevation above water-line on the southern bank of the "Plate," it is built in the form of a parallelogram, the longest diameter run-

NATURAL SIZE OF INFANT'S ARM AT TEN WEEKS.

ning from east to west, the whole being parcelled out into squares, each having a frontage of 150 yards. The houses following the South American fashion, are mostly one-storied, the various apartments opening into small court-yards, called "patios." The streets are paved, but in a most uneven manner, with flagged sidewalks. There is an utter want of sewerage, and no measures are taken to keep the streets clean, the latter being during wet weather, nothing but rivers of mud, and during dry months, dust receptacles. In the eastern and western districts of the town, there are two streets running from south to north, having an incline in the latter direction, which, during the rainy season, become deep and rapid rivers, discharging themselves into the "Plate," and frequently inundating the houses on either side, leaving on their subsidence a layer of mud and deposit, which, under the action of the sun, becomes a source of ill-health to those resident in these streets, and their immediate neighbourhood. The foundation of many of the streets, consists of rubbish and old vegetable matter.

The water-closet accommodation, owing to the absence of sewerage, is well adapted to the production of disease.

A large pit is dug upon the premises; when filled, another is dug close beside it, these pits are at present emptied by means of the air tight carts and hose. The whole city is honeycombed over with them.

Lately, upon the introduction of the water supply by pipes, many persons informed me that the waste water was run off into these pits, with as one would easily believe, a result anything but beneficial. In the centre of each block or square of houses, exists a open space of ground, on which small "shanties," and buildings of a more or less temporary character are run up, in which the lowest class of Italian emigrants live in the greatest state of poverty and dirt, at a charge of about 10d. daily. Such places are termed "Conventillos," and during the late epidemic, served as most prolific breeding grounds for the propagation of the disease.

The epidemic is supposed to have originated from two imported cases, the one coming from Paraguay, the other from Barcelona. It first appeared in the San Telmo quarter, on the eastern side of the town, from whence it spread into the valley, through which one of the two streets already alluded to runs; thence it spread rapidly towards the west, principally affecting such streets, whose foundations consist of rubbish, &c., as already described, and the second of the two river-streets named the "Tercero."

The character of the disease was very malignant, and most intractable to treatment. Commencing with pain mostly affecting the region of the cerebellum and upper portion of the spinal cord, and the lumbar region, irritable stomach, with a sense of oppression in the epigastrium, disordered bowels, dirty tongue, rapid pulse, and a general malaise, in severe cases the fatal symptoms were rapidly developed; great prostration, jaundice, black-vomit and hemorrhage from the mouth, nose, eyes, ears, and anus. A leading feature in the epidemic was the tendency to suppression of urine in most of the cases. As for treatment: emetics in the early stage were tried with, as I was informed, the worst results; the supporters of the mustard baths and sinapisms, calomel and castor-oil method of treatment, speak confidently of its usefulness, whilst most of the practitioners fell back upon the expectant treatment, meeting symptoms as they developed themselves, and guarding as far as possible against the tendency to death. The mortality was fearful, families being decimated, the total mortality being at the lowest estimate, upwards of *fifteen thousand souls*, and probably more. The highest official returns of the daily mortality was 530, but there is little doubt that this figure is too low, as many bodies were carried to the burial ground, without the official order for interment.

Out of one Conventillo, as many as seventy corpses were carried one morning. I regret to say I was

unable to obtain any particulars as to the results of *post-mortem* examinations, neither could I learn that any thermometric observations had been carried out; but when we consider how vast the number of patients was, and the paucity of medical men, such observations could scarcely be expected of them. Out of a population of 180,000, at one time it is thought scarcely more than 30,000 to 40,000 inhabitants remained, all having fled to the camp who could afford it. Viewing the subject in merely a professional point of view, it forms no part of my intention to describe the scenes at, and on the way to, the burial grounds. It was described as something fearful. One burial ground has been closed, and covered with a layer of lime, and earth, and planted, and new grounds opened. It is interesting to note the almost complete absence of cases amongst the shipping, and the fact that though many left Buenos Ayres during the epidemic, yet we have no history of its importation to other ports, or its breaking out on board any of the ships. A similar absence of its spreading is noticeable in the "camp," in spite of the exodus of inhabitants from the City.

This has suggested to my mind the question, was it yellow fever? pure and simple, or was it a fever typhoid in character, and partaking of the symptoms of yellow fever. Certainly the conditions favourable to the production of the exciting poison of typhoid fever are present in a marked degree in Buenos Ayres, and it would be interesting to learn whether in any of the *post-mortem* examinations the characteristic changes in Peyer's glands were present or not. I forgot to mention in addition to the many sources of unhealthy miasm to which Buenos Ayres is exposed, there is a foul stream, the Riachuelo, that runs close to it; and there are large slaughter houses in the near neighbourhood. It is certainly a pity that a town so well placed, and rejoicing in a naturally fine climate, should, through preventable causes, become so unhealthy.

It will be many a long year before the memory of the "plague" of 1871 will fade from the minds of its inhabitants. All honour is due to the medical men and others who bravely faced the danger in the humane duty of giving as far as possible, relief to the stricken ones.

## Hospital Reports.

### KING'S COLLEGE HOSPITAL.

#### *Excision of Hip-joint.*

(Under the care of Professor Wood, F.R.S.)

THE case of hip disease was in a young man, by calling a groom. Some time ago he met with an accident and fell on his hip, and subsequently suffered from extreme debility, the result of long-continued discharge from two large sinuses, one leading directly to the joint, the other opening at a position corresponding with the tuberosity of the ischium. Mr. Wood, in the first instance, made a longitudinal incision over the joint, and subsequently, in order to obtain more room, converted it into a crucial one. Professor Wood then carefully dissected round the joint, and divided the several ligaments. His next step was to remove the head and neck of the femur, first, by sawing through the neck with a convenient saw, having a raised handle, known pretty generally by King's men as "Wood's saw;" secondly, by applying the "lion forceps." Great difficulty was experienced at this stage of the operation, a portion of the head of the bone being ankylosed to the upper margin of the acetabulum; by means of the gouge and elevator the difficulty was overcome, and the head was enucleated. The next step was to remove all diseased portions by means of a gouge, curved forceps, and seques-

trum forceps, as well as cutting away suspicious-looking structures. The second stage of the operation was now commenced—viz., laying freely open the sinus over the tuberosity of the ischium, with a view to ascertain if a communication existed between this sinus and the one that led directly to the joint; none, however, was found. The third stage was to divide the tendons of the hamstrings and biceps muscles, owing to contraction of the knee-joint. The wounds were then carefully sponged and dressed with carbolic acid and oil, the edges brought together by sutures, and a light bandage applied. The patient was then removed to bed, and afterwards an extension splint was applied.

Mr. Wood remarked that here was an instance of caries of the bone, which if no operative procedure were initiated nothing remained for the poor fellow but a lingering death, by reason of the continued discharge from the sinuses, if not death from pyæmia itself. It was always a difficult matter to state precisely prior to operating the exact condition that the parts would be found in in a diseased joint, and what complications the operation itself might present.

As regarded the condition of the joint in this case, there had been adhesion of the head of the femur to the upper rim of the acetabulum. Nature, in fact, endeavoured to repair the injury, and this firm adhesion it was that had rendered the removal of the head so difficult. Again, the carious condition affecting a good deal of the bone, some time was necessarily occupied in removing all the diseased parts, which here included a portion of the shaft, as well as the great trochanter. When the second sinus had been laid open the tuberosity of the ischium was found diseased, and portions had to be removed, which of necessity lengthened the operation; while, finally, there was the necessity of dividing the tendons of the hamstrings and biceps subcutaneously for the contraction of the knee-joint.

Professor Wood, in commenting on the case, said:—Excision of the hip-joint, as a rule, did not present the complications and difficulties that this case did; indeed, in children the head was usually found dislocated, and many of these cases were quite simple in character. Another point worth noticing in operations of this kind generally, and especially in the case under consideration, was the slight loss of blood.

Mr. Wood also drew attention to the condition of the man, which had much improved since he had taken the sulpho-carbolate of iron, and as he believed him to be pretty well "carbolicised," he hoped pyæmia would be averted.

The man has continued to do pretty well since the operation, and his general health has improved. The sinus leading to the tuberosity of the ischium still remains open, due to some carious bone still remaining.

## ST. PETER'S HOSPITAL.

(Under the care of MR. TEEVAN.)

### *Four Cases of Operation for Unusually Large Calculi.*

IN reference to four recent cases the operator, Mr. Teevan, lately made some observations to the visitors—to the following effect:—

The points of interest in these cases are four in number—firstly, that the calculi were very large; secondly, that the method adopted for their extraction was not in accordance with the rules laid down, and generally accepted by the Profession; thirdly, that the patients so operated on all recovered; and fourthly, that the operation was not in any case followed by incontinence of urine. Surgeons usually extract calculi by means of a limited incision into the bladder, and a subsequent so-called process of dilatation, which is, in reality, complete rupture of the prostate

and its capsule. This method is opposed to all the teachings of anatomy, and is usually followed by one of three disasters—death, impotence, or incontinence of urine. Now, I believe that if a free incision be made into the bladder, and the calculus be removed through an aperture which is made by cutting and not by lacerating, we shall greatly lessen the mortality, and entirely abolish such unfortunate sequences as impotence or incontinence of urine. I am prepared to prove that there is no such thing as dilatation of the prostate, and that we ought to adopt a free internal incision, which is in unison with the teachings of anatomy and physiology, and the best surgical principles. I accordingly bring forward these cases to show that by doing that which we are advised not to do, namely, completely dividing the prostate and its capsule, we obtain the happiest results.

CASE 1.—James Birch, a powerful, healthy-looking man, was sent up to St. Peter's Hospital on June 10, 1868, by Dr. Buée, of Slough. The patient had suffered from symptoms of calculus for six years, and for the past two years had, through his sufferings, been precluded from following his occupation. He only passed blood three times, and then after riding in a cart. There was but little pus or albumen in his urine, inasmuch as he had lately led a completely sedentary life. On June 11, I examined the patient with a lithotrite, and found he had so large a stone as to entirely preclude the operation of lithotripsy. On June 15, I performed the lateral operation of lithotomy. Dr. Aspray gave chloroform, and Mr. W. Coulson held the rectangular staff. After I had grasped the calculus, I had to introduce a probe-pointed bistoury four different times to enlarge the wound in a direction downwards and outwards, in order to allow the stone to slide out without the slightest traction being exerted. The calculus was of lithic acid, and weighed four and a quarter ounces. The patient recovered without a bad symptom, the wound being healed on July 16. On July 25 the patient was discharged quite well.

CASE 2.—Robert Wilson, an emaciated sickly-looking man, æt. fifty-five, was sent to me by my friend, Mr. Sebastian Wilkinson, suffering from stone in the bladder, on Aug. 31, 1869. Has experienced much pain for nearly ten years after micturition, and has occasionally passed blood. There was much pus and albumen in his urine. On Sept. 6 I examined patient with a lithotrite, and found that the stone was too large to crack. On Sept. 9 I performed the lateral operation. Mr. Coulson held the staff, and Dr. Aspray gave chloroform. After I had grasped the stone, I had to make three different cuts downwards and outwards to let the calculus glide out without the slightest violence being used. The stone was phosphatic, weighing two and a quarter ounces; it was very flat and oval, its diameter being two and three quarter inches. This patient, although he had no outward symptoms of any kind after the operation, yet had a long convalescence resulting from his great debility, and when he left the hospital three months after the operation, the wound was not quite healed; it was thought that the country air would heal the fistulous track that was left.

CASE 3.—George Evans, a pale, delicate-looking man, æt. sixty-two, was admitted under my care for stone in the bladder, at St. Peter's Hospital, on Oct. 1, 1870. Has had symptoms of stone for three years. After examination I found the calculus much too large to crush. I performed lateral lithotomy on Oct. 8, extracting a phosphatic stone, weighing five ounces. After I had seized the stone, I had to make four cuts outwards and downwards, with a probe-pointed bistoury to let it glide out. The patient left the hospital quite well on Dec. 6. Mr. W. J. Coulson held the rectangular staff.

CASE 4 occurred in Mr. W. J. Coulson's practice. William Griffiths, a healthy-looking man, æt. sixty-five, was operated on by Mr. Coulson on March 5, 1868. The stone was of lithic acid, and weighed four and a quarter

ounces. Four separate cuts were required to liberate it after it was seized. On the 20th of the following month the patient left the hospital quite well. Mr. Teevan held the rectangular staff. All these patients recovered without a bad symptom; the free incision permitted the operation to be rapidly performed, and it then appears that the complete division of the prostate and its capsule are attended with the best results.

WEDNESDAY, AUGUST 2, 1871.

---

### THE DEATH-INJURY OF TALBOT.

THE recent exposure of the tergiversation of the *Irish Times* in the simple statement of the circumstances attending the publication of Dr. Bently's letter on doctrinal midwifery, has had, it would appear, no other effect on the editors of that Journal than to confirm them in the determination, at any cost, to secure the sectarian penny. Accordingly, in defiance of the usually accepted code of journalistic propriety, the *Irish Times* immediately on the death of Talbot, published an article calculated powerfully to influence the result of the inquest, and to protect the assassin from the proper punishment of his crime.

We have not thought it fit to follow the example of the *Irish Times* in reviewing the case *pendente lite*, nor do we now before the trial at the Commission propose to enter on the subject further than to refute the tissue of, let us call them mistakes, to which the *Irish Times*, gave insertion. It is as well to say at once that the object of the article was to show that Talbot was killed not by the man who shot him, but by his surgeon, and *ergo sequitur* that the murderer should be absolved from the gallows; and to give colour to this theory a series of statements were publicly made not only rash but in most instances utterly untrue. We quote the *Irish Times* in its own words:—

“It seems to be the opinion of the medical profession of this city that the wound which ex-Constable Talbot

received in Hardwicke place was by no means of a mortal character. He died of anæmic convulsions supervening, as usual, on extensive hæmorrhage. In probing for the bullet it happened that the surgeon severed the occipital artery. The flow of blood was stopped by pressure, but on Saturday night, for some reason of which we have not been informed, it was deemed advisable to remove the needle by which the pressure was applied. Early the following morning hæmorrhage ensued. In a quarter of an hour the patient lost an imperial pint of blood. The wound was closed as speedily as possible, but too late to prevent fatal consequences. At noon the patient became delirious, refused the stimulants which the medical men endeavoured to induce him to take, and a series of convulsions, lasting for four hours, put a period to his sufferings.”

It is absolutely untrue that any known section of the Profession in Dublin is of opinion that Talbot's wound was “by no means of a mortal character.” The general opinion, we have reason to know, is exactly the reverse, and the evidence of Mr. Porter and Mr. Tufnell on the inquest was explicit and conclusive on the point. The extraordinary circumstance was that a man, with a bullet splintered into many pieces lodged in the base of the skull, with a fractured atlas, an abscess communicating with the spinal canal, inflammation of, and pressure on, the spinal column and its coverings and at the base of the brain, could have lived from Tuesday night to Sunday afternoon.

It is absolutely untrue that “he died of anæmic convulsions supervening *as usual* on extensive hæmorrhage.” The patient never had a convulsion during the entire time he was in hospital, and every surgeon knows that anæmic convulsions are so unusual as to be almost unheard of.

It is untrue that “the flow of blood was stopped by pressure.” During the operation two vessels which were divided in order to arrive at the site of the ball were duly and properly secured by ligatures.

It is untrue that “on Saturday night it was deemed advisable to remove the needles by which the pressure was applied.” On the Saturday night nothing was removed, and no needle was ever applied in order to make pressure on the artery. The tenaculum with which the artery was seized for ligature was removed on Friday, and the statement that “early the following morning hæmorrhage ensued” is untrue.

It is untrue that “in a quarter of an hour the patient lost a pint of blood.” The secondary hæmorrhage which occurred on Sunday morning was immediately arrested.

Lastly, it is untrue that a series of convulsions, lasting four hours, put a period to his sufferings.” Talbot never had a convulsion, but he had the very opposite condition—for he died comatose and with all the symptoms of pressure on the brain and spinal cord.

So far for the facts. The *Irish Times* has acted most improperly—first in prejudging the case; secondly, in publishing a series of inaccurate statements; and thirdly, in exercising its influence to frustrate justice. But its fault has been small comparatively to that of the professional pimp who, while himself secure in his obscurity, whispers falsehoods and aspersions on his profession in the editorial ear. Probably, the honour of the medical detective is worth what is paid for it, and no more. He who sells it loses little, and he who buys will no doubt value it for less when it has served his turn.

## BABY FARMING.

THE Report of the Select Committee appointed to inquire into the best means of preventing the destruction of the lives of infants put out to nurse for hire by their parents has been issued. The Committee first draw a distinction between two classes of cases—first, where the children are put out for hire with the deliberate knowledge, and probably also with the deliberate intention, that they will be sure to die very quickly; and secondly, that class of cases where the children are *bonâ fide* entrusted to the care of others, either in the daytime or by the week, that the mothers may return to, and be enabled to carry on, their usual employments. The Committee have no doubt that baby farming is carried on to a large extent in London and its neighbourhood, as well as in other great towns both in England and Scotland. In its criminal character, the larger number of cases occur in London and its neighbourhood, or in some of the larger towns in Scotland, such as Edinburgh, Glasgow, and Greenock. In the manufacturing districts of Lancashire and Yorkshire carelessness, and not crime, is the principal cause of mortality among children put out to nurse. According to the evidence, which the Committee think indisputable, there are in all parts of London a large number of private houses, used as lying-in establishments, where women are confined. When the infants are born, some few of them may be taken away by their mothers; but if they are to be "adopted," as is usually the case, the owner of the establishment receives for the adoption a block sum of money, sometimes as little as £5, sometimes as much as £50 or £100, according to the means of the person who goes to be confined. The infant is then removed (generally immediately after birth) to the worst class of baby-farming houses, under an arrangement with the lying-in establishments, by which the owners of the baby-farming houses are remunerated either by a small round sum, which is totally inadequate to the permanent maintenance of the child, or by a small weekly payment, varying from 2s. 6d. to 7s. 6d., which is supposed to cover all expenses. In the former case, there is every inducement to get rid of the child; and even in the latter case, unless the mother should come to look after it (which she seldom does), improper and insufficient food, opiates, drugs, crowded rooms, bad air, want of cleanliness, and wilful neglect are sure to be followed in a few months by diarrhoea, convulsions, and wasting away. When the child has not been brought from a secret lying-in establishment, the knowledge of these houses, to which other children are taken, was, until lately, acquired by advertisements in the public newspapers; but since the more respectable of these newspapers have declined any longer to insert such advertisements, it is now obtained, though with more difficulty, by private circulars, secretly distributed. The Committee conclude that nothing can be worse than this class of houses, or more reckless than the conduct of those by whom they are kept. The children born in the lying-in establishments are usually illegitimate, and so are the children taken from elsewhere to the worst class of baby-farming houses. In many cases they are abandoned by their mothers soon after their birth, and in addition to the loss of a mother's care, which is alone sufficient to increase the mortality of infant life to a great extent, they are so culpably neglected, so ill-treated, and so badly nurtured, that, with rare exception, they all of them die in a very short time. Nobody, except the owners of these houses, knows anything more about them; their births are not registered, nor are their deaths; some are buried as still-born children, some are secretly disposed of, many are dropped about the streets. In illustration of this it may be noted that the number of infants found dead in the Metropolitan and City police districts during the year 1870 was—males, 143; females, 121; sex unknown, 12—total 267. And the return made up to the 19th of May in this year shows that there were—males, 51; females, 54—total 105. A very large number of these infants were less than a week old.

On a careful review of the whole evidence, the Com-

mittee have come to the following conclusions:—1. That there should be a compulsory registration of all births and deaths within a limited period after the occurrence of those events. 2. That there should be a compulsory registration of all private houses habitually used as lying-in establishments. 3. That there should be a registration of persons who take for hire two or more infants under one year of age to nurse for a longer period than a day; but so guarded as not to interfere with temporary arrangements of an unobjectionable character. 4. That voluntary registration should be encouraged in the cases of nurses who are not required to register compulsorily.

## SCOTLAND.

## EDINBURGH.

THE JEX BLAKE TRIAL.—At a meeting of the friends of the female medical students, it was resolved to raise a fund to defray the expenses incurred in this trial. Before the meeting closed £249 had been subscribed.

## Notes on Current Topics.

## The late Mr. Courtney, R.N.

WE have to record the death of the late Mr. Courtney, of the navy, who died recently in consequence of accidental blood poisoning. Mr. Courtney, by the present naval regulations, lost three years on half pay, and died only a few weeks before he would have reached the full staff rank. We think the Admiralty should, in a case like the present, give his widow and children the full pension which would have accrued to them had he attained the full staff rank before his death.

## Cholera.

CHOLERA in Russia is, according to last accounts, still increasing at St. Petersburg. There were 13 cases and 4 deaths on the 7th ult. The total number of cases from the beginning of the outbreak being 5,330 of whom 2,198 died. The number of males attacked was nearly double that of females.

The disease has principally increased among workmen employed on the river or in excavating.

Cholera has reappeared in Persia. At Teheran on the 7th June the number of fatal cases was 90; on the 9th 100. It has broken out at Korin, Turcomantchay, Sheriff Shirsey, Kərbela, Nedjeff, Mendili, also at Shiraz and among some Arabs near the Shat-el-Arab River. It has ceased at Kiveit and Bedra. Most dreadful sufferings have been inflicted on the poor by cholera in connection with famine and typhus which has appeared at Teheran.

The facts concerned with the late epidemic of cholera in the 18th Hussars at Secunderabad should, we think, be strictly investigated. It may be attributed in a great measure to the use of unwholesome water drawn from a polluted well. The barracks at Secunderabad also have long been considered unhealthy.

## Enlarged Tonsils.

DR. RUMBOLD, St. Louis, Mo. (*Med. Archives*), has treated successfully a number of cases of enlarged tonsils by injecting the glands by means of a hypodermic syringe,

with a solution of iodine—iodine, gr. ij. ; potass. iod., ℥ ij. ; aquæ, ℥j. From twelve to seventeen injections—ordinarily two a week—were sufficient to reduce the gland to its normal condition. The advantage claimed for this mode of treatment was, saving the substance and function of the gland.

### Typhoid Fever in Belgium.

IN the last session of the Council the burgomaster delivered a speech in which he said it had been too hasty and premature to accuse Brussels of being a hotbed of infection.

M. le Dr. Warentrapp, the medical savant of Frankfort, in a comparative table shows that Brussels instead of being the most unhealthy city of Europe, in reality suffer less than any capital from typhoid fever. The rural districts, however, and united towns of Belgium suffers severely. The following are the number of deaths due to typhoid fever per 100,000 inhabitants, for a few cities, according to his table—viz. : Brussels, 6·23, 1862-65 (least of any) ; United cities of Belgium but a little more, viz., 9·2 from 1851-60 ; Rural towns, 10, 1851-60 ; La Haye, 6·31, 1857-55 ; Frankfort, 6·8, 1851-65 ; Munich, 29·1, 1865-66 ; Amsterdam, 14·1, 1854-62 ; and London, 9·3, 1851-64.

The Burgomaster proposes a gigantic scheme of disinfecting the Senne at an estimate of six millions of francs.

### An Enormous Dose of Opium.

A YOUNG man, aged twenty-four years, says the *Shanghai Budget*, quarrelled with his brother, and then swallowed nearly 240 grains, apothecaries' weight, of crude opium. Twelve hours subsequently a native physician was called in. The soporific effects of the opium had so far passed off as to enable this celestial to sit up in bed, converse freely, and to swallow large quantities of mustard and water. The two following days he suffered from headache, lassitude, profuse perspirations, and bronchitis, consequent on engorgement of the lungs. He never vomited, was not an opium smoker, and made a good recovery.

### Society for Organising Charitable Relief.

AT the last meeting of the Society for Organising Charitable Relief, Sir Charles Trevelyan reported the result of the recent deputation from (1.) The Committee appointed to inquire into Out-patient Hospital Administration in the Metropolis ; (2.) The "Metropolitan Branch of the British Medical Association ;" (3.) The "Poor-law Medical Officers' Association," and (4.) The "Society for Organising Charitable Relief and Repressing Mendicity." Mr. Stansfeld, he reported, cordially acknowledged the value of voluntary efforts in aid of the legal or regular forces in lessening social evils, and said he was desirous of freely conferring with members of the Societies represented by the Deputation. Assuming the object of the Deputation to be that, as a general rule, there should be no gratuitous medical relief except through the Poor-law, he explained that the Poor-law Board were urging forward the completion of the arrangements required under the Act of 1867, for giving effectual medical relief. The pauperising influence of indiscriminate medical out-door relief was strongly and repeatedly urged by the Deputation,

and Mr. Stansfeld was invited to discourage the practice and to promote the conversion of the present Free Dispensaries into Provident Dispensaries. In reply, Mr. Stansfeld pointed out that the Poor-law Board could not control the free action of institutions supported by voluntary contributions, and that this could only be done by appealing to the public, and by influencing the organs of public opinion to stop such evils by exposing their dangers which duty seemed more properly to belong to the Charity Organisation Society. Mr. Stansfeld also expressed his preference for a local rather than a centralised system, and he thought that, although local action caused delay sometimes, yet that, on the whole, it worked better than the over-ruling and over-governing found in a centralised system.

### Metric Measures.

THE defeat of Mr. Smith's Bill for the introduction of the Metric System at this late period of the Session, in presence of an unprecedented Legislative block, after the promise of the Government to legislate next year, and by the narrow majority of five votes, bears conclusive evidence that before many years we shall have forgotten our multiplication table, and abandoned the use of inches and ounces. It is needless to say that, with all the inconveniences of so repulsive a change before us, we very earnestly desire the passing of such a Bill. We don't go, as Mr. Smith did, to Magna Charta for our reasons. It is sufficient to know that there are two different systems of weights and measures existing in the United Kingdom—that 66 per cent. of our financial transactions with other nations have to be put through a complex arithmetical process before they become comprehensible, and that our simplest calculations involve a troublesome business of adding, dividing, and multiplying. The respective merits of the duo decimal and the decimal systems are, of course, subjects for diversity of opinion ; but, supposing the superior convenience of the decimal system to be proved, there ought to be no second opinion as to the propriety of its general adoption. It will, no doubt, take years to eradicate the old system, and introduce the new ; but there is no difficulty in making the process a gradual one, and thus obviating too violent a revolution.

### The Ravages of the War.

THE Medical Department of the Prussian Ministry of War publishes a Report, from which we glean that during the recent lamentable war with France, 101 Prussian surgeons died in the field, or were disabled by wounds ; also sixty-three were wounded (two of them each twice over). Twenty-five died of disease ; four of these from dysentery ; eight from typhoid fever, and one from a combination of both.

### Accidental Poisoning.

THE position which we have taken with regard to the protection of the public from accidental poisoning, and to the Bill introduced by Mr. Forster for that object, has been designated by the *Pharmaceutical Journal*, in its last issue, as "a totally unnecessary and gratuitous attempt to aggravate a contest which was already too dominant." We should regret that our efforts in the matter were open to any such interpretation, but we cannot charge ourselves with any such result, either in intention

or effect. So far as the vigorous advocacy of one side in a controversy can be so described, we are open to the charge; but we do not consider that the intervention of a medical journal, in such a way, can justly be called gratuitous or unnecessary.

The *Pharmaceutical Journal* considers that the following phrase carries with us its own condemnation:—"A larger issue than poison-protection is at stake, for it has now to be decided whether the Government is able to deal with an opposition dictated, not by any principle, but by self-interest and carelessness for the public interest." Well, we have re-read the phrase, and we see no reason to modify it. We are sorry to "speak evil of dignitaries," but we are bound to say that we have failed to discover, in the proceedings of the Association and Committees who opposed the enactment of poison regulations, any higher "principle" than self-interest.

The entire burthen of their song was, that, as the cases of poison were few, it was not necessary or proper to inconvenience druggists by obliging them to observe precautions in the care of poisons. We don't agree in that view. Accidental poisoning ought to be, as nearly as may be, impossible; and no amount of inconvenience to traders ought to prevent the risk being reduced to a minimum.

The Council of the Pharmaceutical Society are, in our opinion, far more censurable than the body of opposing druggists. They accepted from Parliament a trust for the protection of the public—they delayed and obstructed the discharge of that trust, and, being at length forced into action by the Privy Council, they stultified themselves by reversing their policy in deference to trade clamour. It is plain that they had no principle in the matter. If they felt that they were forbidden by the Society to do that which they had promised, they would have consulted their own honour rather by resigning their seats, as Mr. Sandford did, than by holding office by a sacrifice of their expressed opinions.

### The Small-pox in London.

A CONTINUED decrease is shown in the small-pox epidemic by the returns up to Saturday. There was a return to a higher figure the week before. The returns of the Metropolitan Asylums Board's hospitals showed a continued increase of vacant beds. Since the opening of the Stockwell Small-pox Hospital 944 vaccinated and 390 unvaccinated patients have been received, in all 1,334. The total admitted since the opening had been 636 vaccinated, and 446 unvaccinated, in all 1,082, of whom 32 vaccinated and 154 unvaccinated had died. A deputation waited upon the Board from Hampstead and urged that the erection of the hospital in that district had been detrimental to the value of property there. The deputation offered to give the Board a site in exchange for that at Hampstead. Dr. Brewer assured the deputation that their request would be taken into serious consideration, but at the same time he reminded them that the Board had to consider the necessities of the metropolis as well as the wishes of Hampstead or of any other district. After the deputation had withdrawn, the subject was debated at great length, and eventually a resolution which virtually gave a negative answer to the request of the deputation was carried.

### Cholera.

The *Journal de Saint Pétersbourg* of the 21st ult. says:—The *Police Gazette* of St. Petersburg published on the 18th ult., the following return of cholera cases—patients, 518; new cases, 67; cured, 33; dead, 27. The same newspaper stated that on the 19th inst., there were still under treatment 525 persons. Since the appearance of cholera on the 29th of August, 1870, to the 19th of July, 1871, there have been 6,072 cases, 3,040 cures, 2,485 deaths. The *Caucasus* newspaper says it is known from reliable sources that the cholera which has this year broken out in Persia originated at Ardebil, on the routs from Taurida to Sirab and Zandrak.

### Dr. Jenner.

ALMOST the only living relative of the great Dr. Jenner who bears his name is an aged man now living on 10s. a week in a poor cottage at Heathfield, in the parish of Berkeley.

Mr. Stephen Jenner is the grandson of Dr. Edward Jenner's brother. He was educated for the medical profession, and as a lad was a constant companion and guest in his great uncle's house. He was, indeed, the only person present with him at the breakfast table when Dr. Jenner received the apoplectic stroke of which he died. "There is no person living," says Mr. Jenner in a letter of July 19, "who knows so much of Dr. Jenner's social and domestic life as I do." He is now seventy-five years of age, in very bad health, bearing the ills of life uncomplainingly, not wishing to intrude them upon society.

### Effect of Electricity on Plants.

MR. BECQUEREL has presented to the Academy of Science of Paris a memoir, in which he shows that the discolouration of flowers, leaves, and even roots may be effected by the direct and immediate action of electricity. Fifteen or twenty minutes action is sufficient to remove all colour. The red on the surface of certain leaves was removed to the green underside, but the inverse effect has never been obtained.

### A new Physical Law.

FOR the purpose of verifying and measuring the force evolved in the dilatation of water in freezing, which has been known to be sufficient to burst cannons, M. Bousingault has discovered an important fact by means of a very simple experiment. He filled, very exactly, a steel cannon with water at a low temperature, and having introduced into it a steel needle, closed it hermetically. When this apparatus was placed in a temperature of 23° below zero it was ascertained, by the sound of the needle falling through it when it was turned upside down, that it was not frozen, but the moment it was opened the water solidified immediately. It is proved by this experiment that water placed in such condition that it cannot dilate, is incapable of being frozen.

### Potable Sewage.

A CORRESPONDENT of the *Times* stated last week that the River Calder receives, through the Ribble, the sewage of Halifax, with 40,000 inhabitants. It receives, before it reaches Wakefield, the sewage of several smaller towns; it then receives that of Wakefield itself, with

some 36,000 inhabitants; and, four miles below this last town, the water is pumped out of this same river, filtered, and sent back to give drink to its inhabitants.

Again, one of the main sources of water supply of Birmingham—something like 17 millions of gallons per day—is the Bilston Brook, after this stream has received into itself the filth of Bilston. And, another correspondent describes how the Don, rising near Penistone, flows through Sheffield, receiving the sewage of that town's 240,000 inhabitants, and above Rotherham is joined by the Rother, charged with the filth of Chesterfield (10,000 inhabitants). The river passes through Rotherham (27,000 inhabitants), where it is allowed to flow in so large a bed that the greatest possible extent of its perfume is enjoyed by that town, which adds its quota, and the unhappy river flows on with its disgusting burden to Doncaster (20,000), which town has no other water, and so by Thorne and Goole to the sea.

He asks, are all our influential members of Parliament too much engaged with the Ballot Bill, or political humbug of one sort or other, to stir that deadly pool of lethargy whose stagnant waters permit our helpless millions to poison each other? Are we not totally unprepared for the enemy, and yet he threatens us? Have we no fear for our wives, daughters, sisters? Let all who have talent, influence, power, or will, do what they can. There are many who have none of these qualifications, or lack at all events the last.

#### Effect of Bad Food on Human Lactation.

THE observations of Dr. Ducaine on the modifications undergone by human milk, during the siege of Paris, result in the following conclusions:—

1. The effects of insufficient food are, in the female, very analogous to those in other animals.
2. The effects vary according to the constitution, age, hygienic condition, &c.
3. Bad feeding determines in variable proportions a diminution in the equivalent of butter, caseine, sugar, and salt, while it increases that of albumen.
4. In three-fourths of the cases, the proportion of albumen after bad feeding is in inverse proportion to the caseine.
5. An improved diet makes itself manifest in a remarkable degree, by the composition of the milk, within a few days.

DR. C. BASTIAN is to have the full title of physician to University College Hospital.

THE BISHOP OF CHICHESTER opened the Brighton Hospital for Sick Children on the 14th of July.

AT the Quarter Sessions recently held at Bridgewater, Reed, Bovett, and Roberts were each fined £5 for refusing to have their children vaccinated.

THE staff-surgeon of H.M.S. "Narcissus," flag-ship of the Channel Squadron, has been called upon to refund all the additional pay he has drawn as surgeon of a flag ship. The *United Service Gazette* says, "If extra pay is allowed to officers serving in flag-ships, there should be no exceptions."

THE Chairs of Zootomy, or Comparative Anatomy, and of Cattle Pathology in the Edinburgh Veterinary College are now vacant.

THE surgeoncy of Chatham Dockyard will shortly become vacant by the retirement of Staff-Surgeon Piers, Royal Navy, on half-pay.

BY the resignation of Dr. Murchison, F.R.S., Physician to the Middlesex Hospital, a vacancy is declared. And another by the resignation of Henry Arnott, Esq., Assist.-Surgeon to the hospital.

A SUMMONS under the Sanitary Act, taken out against Mr. Davis, surgeon, of Isleworth, for causing a person suffering from contagious disease, viz., small-pox, to expose himself to the public peril by travelling to London in a railway carriage, has been adjourned for a week.

TWENTY-ONE thousand six hundred and twenty-five persons were arrested in London in 1870, against 20,391 in 1869, for being drunk or drunk and disorderly. Is one person arrested in 500 of those who get drunk? At that proportion about eleven millions of persons are "incapable" annually in London.

THE following members have been elected Fellows of the Royal College of Physicians of London:—Dr. Bishop, Paris; Dr. Leard; Dr. Child, Oxford; Dr. Hitchman, Mickleover; Dr. Drake, Southernhay; Dr. Copeman, Norwich; Dr. Wade, Birmingham; Dr. Frank; Dr. Stevenson, Guy's; Dr. Theodore Williams; Dr. Tilbury Fox; Dr. Waring; and Dr. Hensley.

AT a meeting of the Westminster Hospital Weekly Board, on the 25th ult., to receive applications for the surgeoncy and assistant-surgeoncy, Mr. Pearse, senior assistant-surgeon, was recommended for the post of full surgeon. Two gentlemen, Mr. Cooke and Mr. Roberts, intend canvassing for the latter. The election will come off on Friday.

FOUNDER'S DAY was celebrated at the Epsom Medical College on the 20th ult. The annual Prefect's breakfast was celebrated, followed by chapel at 1.45, when the speeches came in the school-room. The head-master gave notice that Mr. Erasmus Wilson had signed a cheque for the erection of the first master's house. The health of the school is good, illness being confined to slight colds. Nearly all have been revaccinated.

OUR readers will no doubt recollect the case of the death of a young man in Camden Town a few weeks ago said to have been hastened by the administration of strong purgatives by a herbalist who attended him. A case of a somewhat similar nature has occurred at Hull. The patient was Anne Dowsland, æt. forty-seven, suffering from asthma, &c., and she was attended by a Mr. Robinson, a herbalist, who administered pills containing amongst other ingredients—jalap, alocs, ginger, and cayenne! He charged 2s. 9d., and said he would call again in the autumn. He alleged there was swelling at the chest which wanted removing. The patient was

much purged, and complained of severe internal burning pains. She took some of Rooke's pills at the same time. A *post-mortem* was made by Dr. Alison who found the lungs congested and all other parts healthy with the exception of some feet of intestine which were highly inflamed. He agreed with Dr. Nelson that the medicines given had hastened death, and the jury passed a verdict to that effect.

The above facts need no comment, for any reader can draw his own conclusions. The law should be amended to put a stop to this state of things, and prevent quacks prowling about thus.

## SPECIAL CORRESPONDENCE.

PARIS, JULY 27.

(FROM OUR OWN CORRESPONDENT.)

I SEND you a few particulars on the subject of cremation of corpses on the battlefield as practised by M. Lanty and M. Créteur at Sedan and other places. I briefly mentioned the subject in my last letter, but as M. Lanty has published an account of his labours I have been enabled to gather a few additional particulars. I need not pause to describe the mode of proceeding as I have no doubt your readers are well acquainted with it. The cremations and disinfections were conducted by the well-known doctor, M. Lanty and M. Créteur the chemist. They were originally commenced in the Champ de Rubecourt, and proved so successful that they were continued on the territory of Lamoncelle. From the 10th of March up to the 25th of April cremation was the only mode of disinfecting employed by the Belgian Government. "This manner of operating was, however," says M. Lanty, "antipathic to the officers of the Bavarian Army, and after some official notices we received one day the order to burn no more corpses belonging to that army." It was however next to impossible for M. Lanty to act in accordance with this order, for in the greater number of the incinerations the bodies were buried without any respect being paid to nationalities—Frenchmen, Prussians, Bavarians, Saxons, and Wurtembergers being often thrown together in the same grave. "We made observations to the superior German authority," continues M. Lanty, "which at first authorised us to continue, but ended by ordering us to discontinue the burning of German soldiers." It was only after many interviews, and through the active intervention of M. Albert Brun, acting sub-prefect of the district of Sedan that the different obstacles offered to the satisfactory progress of the work of M. M. Lanty and Créteur were finally removed. From that time (March) their labours proceeded without interruption up to the end of April last, and were extended from the towns already mentioned—viz., Rubecourt and Lamoncelle—to those of Sedan, Givonne, Balan, Bazeilles, Douzy, Daigny, Illy, Floing, Torey, and Beaumont. In the three latter towns, however, burning was not exclusively employed; but M. Michel, an engineer, made use of his system in 902 graves which I shall describe hereafter.

M. Créteur's operations comprised the disinfection of 3,215 graves (or nearly four times as many as M. Michel) of which 1,986 contained human bodies, and 1,227 those of animals. On an average there were not less than twenty men in each grave, making a total of 39,720 (*human*) corpses; of horses about on an average five (on the banks of the Meuse twenty) in each grave, or a total number of 6,135 horses. The total number of bodies (men and horses) according to the above account, were not less than 45,856, of which three-quarters had been burned.

Not less important results were accomplished in the

plains of Bellevue and other places, where 1,500 to 2,000 corpses of horses and oxen were accumulated hardly covered by a thin layer of earth.

I will now give a brief account of M. l'ingénieur Michel's mode of procedure, or system of *surélévation des tombes*. M. Michel disinfected 902 graves, extending over an area of 9,000 metres. The bodies were put in the graves naked, and covered with—1. A thick layer of lime; then, 2. A layer of earth; 3. Another, but thinner layer of lime; and then a mound raised with a large base which reached the height of 1 metre 95 cent. to 2 metres according to the importance of the grave. The tumulus thus formed was surrounded with ditches which in assuring the flowing away of waters prevented their stagnation and corruption.

## HOMŒOPATHY—ITS PRINCIPLES EXPLAINED.

(Continued from page 84.)

### LECTURE II.

DR. EPPS commences his second lecture not by a fulfilment of his promise to define homœopathy, but by an attempt to account for the cures that have been performed in all ages of the world. His explanations are twofold.

He says that—"1. The new disease instituted by the counteraction of the allopathic treatment has afforded a suspension of the diseased action, and has allowed the natural powers of the system to effect the cure under the existence of that suspension. 2. That the cures, when not effected in this way, have been effected by the medicines prescribed being homœopathic to the diseased states."

1. With regard to his remarks on allopathy the Doctor seems extremely inconsistent, probably arising from the apprehension of truth which may yet remain in his mind. He quotes in 1841 words to prove the "unscientific character (!!) of the allopathic mode," which were written by himself (!) in 1832 to show that counteraction was a most valuable and scientific mode of treating certain classes of disease.\* Thus is the Doctor driven about on the waves of opinion or prejudice—one day eulogising a particular mode in which he "has had more practice than most men," and another deserting what lately brought him fees and fame for some more novel way of impressing the public. Perhaps his considerate treatment of counteraction, which he acknowledges often cures (how can he deny that which he before took such pains to prove?) arises partly from the following words occurring in the twenty-ninth chapter of the "Homœopathic Bible."

"As every disease depends only on a particular morbid derangement of our vital force in sensations and functions, when a homœopathic cure of the vital force deranged by the natural disease is accomplished by the administration of a medicinal potency on account of a similarity of symptoms, a somewhat stronger but similar artificial morbid affection is brought into contact with, and as it were pushed into the place of the weaker, similar, natural morbid imitation, against which the instinctive vital force, now merely (though in a stronger degree) medicinally diseased, is then compelled to direct an increased amount of energy; but on account of the shorter duration of the action of the medicinal potency that now morbidly affects it, the vital force now overcomes this, and as it was in the first instance relieved from the natural morbid affection, so it is now at last freed from the artificial (medicinal) one, and hence is enabled to carry on healthily the vital operations of the organism.†"

If these cumbersome lines convey any meaning to the reader it must be that homœopathy is a species of counter-

\* "On Counteraction, &c." By John Epps, M. D. Renshaw and Co., 356 Strand.

† Hahnemann. "Organon."

action set up in the part affected, rather than in a part "less essential to life." Common sense will easily determine which of the two is the more preferable. In the words of the late eminent and lamented Dr. Pereira—"Homœopathic remedies would only increase the original disease, and we can easily imagine the ill effects which would arise from the exhibition of acid in gastritis, . . . or of mercury in salivation."

2. He tells us that the remaining cures "have been effected by the medicines prescribed being homœopathic to the diseased states." He makes no bones of telling the faculty that no physician before Hahnemann "knew anything about the action of remedies." Homœopaths boldly throw accusations of ignorance against other men, and live upon the injury they inflict upon them, thus rendering themselves liable to fines and expulsion from the "College of Physicians." Comparatively few, however, are members of that body, and, we believe, none are Fellows; or it would be probable the "College" would stoop to clear itself of all connection with such men. If it did not it would soon forfeit the confidence of both the profession and the public. But to return from this digression. Dr. Epps surely cannot be aware of the double edge of the weapon he employs. We must then take the liberty of telling you Dr. Epps that *mutato nomine de te fibula narratur*. The antipathics may just as well say that all cures you have performed are "effected by the medicines prescribed being antipathic to the diseased states." What say you to that Dr. Epps? Is your opinion to outweigh that of the hundreds of thousands of intelligent observers from Hippocrates to the present time. Will "intelligent minds" prefer the *ipse dixit* of "John Epps, M.D.," to the experience of ages and the observations of the most profound thinkers who have graced the annals of science? We can confidently leave the question for their consideration.

It is easy to perceive that Dr. Epps has not satisfactorily accounted for those cures the reality of which he does not pretend to deny.

Again, Dr. Epps comes to the question "What is homœopathy?" And as an answer thereto we are treated to a life of Hahnemann. In the hands of a Dickens or a Thackeray it is probable that the life of such an enthusiast would have turned out an amusing or powerful satire, which would amply have served the purpose of the present humble performance, but in the hands of "John Epps, M.D., &c.," it merely turns out bare, and our readers will be very thankful that we have neither space nor inclination to quote much of it. The "turning point" in his life is thus stated:—

"In translating (in a work of Cussens) the article on Peruvian bark he was much struck with the account given of the febrile or fever expelling properties of this valuable remedial agent. He determines to try it upon himself (a mark of that decision of mind so essential to investigation), and being in the enjoyment of robust health began his experiments. The first dose produced symptoms in him similar to intermittent fever or ague, which bark so often effectually cures. The resemblance between these symptoms and those which are presented in intermittent fever, for which he knew this remedy was famous, so struck him, that he was in a moment of inspiration, thus breathed upon his dormant genius, but to glance at, and to discover the first lines of the truth written in creation, that the law on which the beneficial application of all medicines is founded is this, that medicines cure diseases by their power to produce, when taken by healthy persons, symptoms equally similar to the disease they cure."

This is the only way in which Dr. Epps condescends to answer his own question, and this is his only definition of homœopathy, but we are content to take it such as it is. We have serious doubts about "the first dose producing the symptoms of ague!!!" from the fact that scarcely any one but Dr. Epps puts in the words "first dose;" and out of the thousands who have endeavoured to produce the same effects there are not half a dozen who can testify to

the truth of Hahnemann's experience. Any reader can try it for himself, and he need not fear any ill consequences. But even granting this to be true, who would not be struck with the fact even from Dr. Epps' narration that Hahnemann upon a single experiment, liable to many fallacies, "in a moment of inspiration" (we should rather call it enthusiasm), built up a theory relative to all matter, and then looked for support for it. He reasons from particular to general; he is caught with a notion of some possibility of a discovery, and straightway tries to prove it—all the time protesting that he was led by experimental research to adopt these views. On this slight and sandy foundation, just as the last stone is put up, he sees his building cannot stand, and accordingly sets to work at once to prop it up with the most handy materials for the purpose. To these Dr. Epps solicits attention:—

Prop No. 1.—"If a person burns his finger and holds it to the fire in a short time his finger will be cured." Doesn't that prove the law? Doesn't heat cure a burn? We believe not. We may not be such profound philosophers as our friend Dr. Epps, but we are fully aware that however captious he may be, heat and cold are but relative terms. To a hand at 80° Fahrenheit 90° will be hot and 70° cold. To a hand at 120° a temperature of 80° would be cold. The holding the burn to the fire is then actually applying cold. No one would think of applying a temperature to a burn of the same degree that caused it. The only homœopathic cure for a burn from a red hot iron would be the application of an iron at a white heat. We advise the Doctor to say no more of Prop No. 1.

(To be continued.)

## Parliamentary Intelligence.

### CHOLERA.

IN the House of Lords, on Thursday last, the EARL of CARNARVON asked whether Her Majesty's government were prepared to take any, and if so, what precautions as to the supposed approach of cholera. The question concerned the welfare of a great number of people in the country, and it was desirable that Her Majesty's government should be able to answer it satisfactorily. It was said that cholera was rife in European Russia, and was gradually moving in this direction, and had advanced, according to a statement published that morning, upon the German frontier, having appeared on the banks of the Niemen, and might be expected to reach Germany within two or three weeks.

The EARL of KIMBERLEY was glad that a question of this kind had been put to him, because to this extent it was unfounded, that in Russia and Poland the existence of cholera was by no means a new fact, having existed in Russia for the last two years. It had indeed appeared rather nearer to Germany, but there it had existed since last April, as it had in the western provinces in Russia. Now he did not say that cholera in Russia was not to be taken notice of, but that no new facts had arisen. No intelligence had reached them of any case occurring in Germany. They had, however, instructed their representative in Berlin to make all necessary inquiries, and to say whether the German government had taken any special precautions. As regarded the practical matter now under consideration, he could only say that if it was in the power of the government to do anything they would do it. But the fact was, it rested almost entirely with the local authorities, who had been constantly told of the precautions they should take. The water supply was a question of great importance, because in the opinion of many most competent persons it was through water the cholera was propagated, and, in any case, there were quite sufficient

grounds for making every one anxious that the water supply should be as pure as possible. There was another measure now passing through parliament which he hoped would have some good effect if passed into law this session, giving, as it would, the local authorities additional power of dealing with these questions. He meant the bill concentrating all powers in regard to health into one department, which he thought would lead to many useful reforms.

In the House of Commons on the same day, the subject was introduced by Mr. Gathorne Hardy, and replied to by Mr. Forster, in much the same strain as in the Upper House.

#### REPORTS OF THE MILITARY MEDICAL OFFICERS SENT TO THE FRENCH ARMY.

ON Thursday, July 27th, DR. BREWER asked the Secretary of State for War, if he would lay upon the table of the house so much of the reports of Drs. Gordon and Wyatt in relation to their recent sojourn in Paris, and in connection with the French army, as would throw light upon the character and treatment of wounds received during the late war and siege, and any successful or defective system of hygiene which the reports might contain for the guidance or caution of the military or civil medical and surgical profession.

MR. CARDWELL had to report what he had said once before—that these reports were the result of a visit made by officers to a foreign army, by whom they were received with the greatest friendliness and were treated with the greatest confidence. He was not at present prepared to say that he should be ready to place any extracts whatever from these reports upon the table of the House.

#### THE MEDICAL SERVICE IN INDIA.

COLONEL SYKES asked the Under-Secretary of State for India whether Drs. Gopal Chunder Roy, and Krishna Dhurr Ghose, who came to England to compete for commissions in the Medical Service in India, and had obtained the prescribed degrees in medicine and surgery, but were debarred from reaping the reward of their studies and outlay by the competitive examinations being from time to time postponed on the ground of medical officers not being required in India, might, nevertheless, be now allowed to compete, with a view to their being placed on a supernumerary list to fill up vacancies as they occur, to avoid otherwise the total and grievous loss to their time and money, as their present ages would debar them from competing at any future examinations.

MR. GRANT DUFF.—I regret that we have no powers to do what my hon. and gallant friend wishes. When the Government of India informs us that it wants such and such a number of medical officers, we announce that such and such a number will be selected by competitive examination, but we cannot ask some score or hundred medical students to enter for a competitive examination, in which the prize would be the chance that the successful candidates might at some indefinite future period be employed as Indian medical officers. I don't think that would be a fair proceeding either to the medical schools or to the Government of India.

COLONEL SYKES asked when the next competition would be held.

MR. GRANT DUFF.—I have not the remotest idea. (A laugh.)

#### OBITUARY.

CHARLES NEILSON, M.D., F.R.C.S.I.

KILLALA, CO. MAYO.

DR. NEILSON died on the 15th ult., aged seventy-four years. He was a native of Co. Down, and received his education at the famous seminary of his grandfather, the Rev. Moses

Neilson, D.D., Redemon. He early manifested a talent for languages, having been familiar with the Greek grammar at the age of seven years, and also a similar aptitude for medical science, illustrated by the fact that when only twelve years of age, he was able to amputate a limb in Dundalk Hospital, where he was initiated in surgery, under the late Dr. Noble.

He studied in Dublin, and in 1824, took out his diploma in the Royal College of Surgeons, where he highly distinguished himself at the several examinations. He was elected a Fellow of the College in 1844. He began as a practitioner in Killala, and on the establishment of the Poor-law system in Ireland, became the Medical Dispensary Officer of the Killala Union. During the lengthened period of forty-six years' practice, Dr. Neilson was most successful in each department of his profession, having won the confidence of all classes by his skilful treatment of disease, while his urbanity of manner, combined with a genial and liberal disposition, endeared him to a large circle in the community, who now mourn his removal. In the years 1832 and 1849, when cholera ravaged the district, he was most active and successful in his treatment of that terrible epidemic, while his views on the subject which differed from those of many others at the time, have been since confirmed by later therapeutical investigations. He always manifested literary and scientific taste of a high order, and kept up an extensive reading in medical, theological, and modern literature. For several months past, he suffered severely from acute disease of the heart, which terminated in his death on the above date.

#### Literature.

#### THE DUBLIN PRACTICE OF MIDWIFERY.\*

WE have before us a new edition of this once popular treatise on midwifery, edited by Dr. Thomas More Madden, senior assistant-physician to the Rotunda Lying-in Hospital. In size and general get-up there is little change in the book. The editor tells us, in his preface, "that the chief subjects in which alterations and additions have been made are, the twelfth chapter on the forceps, which has been completely re-written. The fourteenth chapter on the treatment of hæmorrhage has been considerably enlarged and altered, and additional chapter on the present type and treatment of puerperal fever has been appended. The following chapters "On the Third Order of Difficult Labour," "On Version in Cases of Pelvic Deformity," "On the Cæsarean Section," "On the Induction of Premature Labour," and that "On Inversion of the Uterus" are all entirely new."

As we have on more than one occasion expressed our opinion upon the merits of this work, we intend at present only to call the reader's attention to that portion of the book which contains the additions and alterations for which Dr. Madden holds himself entirely responsible. We fully agree with the editor's remarks in opening the twelfth chapter, that,—“The chief aim of the art of midwifery has been defined to be the safe delivery of a living child from a living mother. There can therefore be no chapter in a manual of midwifery of greater practical interest than that which treats of the method of accomplishing safe parturition in cases which must terminate unfavourably, to either the mother or the child if nature be not assisted by art.” We regret that we cannot look upon the chapter before us as either carefully written or

\* "The Dublin Practice of Midwifery." By Henry Maunsell, M.D., formerly Professor of Midwifery in the Royal College of Surgeons, &c. New edition, enlarged and revised. Edited by Thomas More Madden, M.R.I.A., L.R.C.C.P.I., M.R.C.S. England, L.F.P., &c., Glasgow. Senior Assistant-Physician Rotunda Dublin Lying-in Hospital. London: Longmans, Green, and Co., 1871.

interesting, and the student who depends for his knowledge of the forceps on this chapter, will find himself in an awkward position while undergoing the ordeal of an examination. Although the editor alludes to two varieties of forceps, the long and the short, he only describes an instrument which he tells us he prefers "the measurements of which are ten inches in length from the handle to point. The blades,  $6\frac{1}{2}$  inches long, the widest space between blades when locked  $2\frac{3}{4}$  inches, the space between the points  $1\frac{1}{4}$  inches. The total weight of the instrument,  $8\frac{1}{2}$  ounces, and a ring is introduced into the lock into which the fingers of the operator are introduced during the extraction. The fenestra are very wide in proportion to the width of the blade, and so thin, that when the forceps is applied the scalp over the parietal bones projects in such a manner, that there is comparatively little risk of the maternal structures being injured by the instrument."

These Lilliputian forceps, which we suppose are for the future to be styled "Madden's forceps," are the only instruments brought under the student's notice. Now we have not the slightest objection to Dr. Madden having a preference for these—to our mind—miserably impotent instruments, but we cannot allow him to launch them before the public as the "Dublin Midwifery Forceps," without stating that such they are not, for to our certain knowledge the instruments used both at our Lying-in Hospitals and in private practice are Drs. Beatty and Churchill's forceps. There is a slight allusion made to the curved forceps of Dr. Barnes, which the editor states he has occasionally resorted to, but he leaves the reader to find out in some other quarter the peculiar characters of the instrument. The *vecis* is disposed of in a few well written lines. We regret that we are compelled to speak unfavourably of this chapter, and more especially as it has been completely re-written for this edition by the senior assistant master of the Rotunda Lying-in Hospital, but we feel that it would be unfair alike to the student and the Dublin school of midwifery not to express our opinion freely upon this, the most important chapter in the book.

The fourteenth chapter has some valuable additions, such as Dr. Barnes' treatment of post-partum hæmorrhage by the injection of a solution of perchloride of iron into the cavity of the uterus, a treatment which we believe has been carried out with much success in Dublin practice. Also Dr. Robert McDonnell's improved and simplified method of performing transfusion.

The chapters on craniotomy and the Cæsarean section are badly written, and are for the most part the editors own views, which are opposed to the most eminent authorities of the present day, and of course as such cannot be looked upon as representing fairly Dublin practice. The cephalotribe is disposed of in ten clumsily written lines. We cannot, however, wonder at this, for Dr. Madden tells us "that never before or since his connection with the largest lying-in institution in Great Britain has he ever performed on a living child what Dr. Radford has described as that dreadful expedient nay, shall I not call it murderous operation, craniotomy."

We will not at present go any further, for we believe we have said enough to show the reader that we entirely disapprove of the book in its present form, and cannot recommend it as the old popular Dublin practice of midwifery, and while we trust that we have said nothing in any way disrespectful to the editor, of whom we entertain the highest opinion, we felt it to be our duty to speak plainly, as the very title of the book involves the character of the Dublin School of Midwifery. We hope, however, on a future occasion, to have a pleasanter duty to perform, viz., that of lending our aid to re-instate this book in its once exalted position.

#### LECTURES ON AURAL CATARRH.\*

The subject treated of by Dr. Allen in his lectures and

now submitted to the profession in a compact volume, is one of the most frequent causes of deafness, and as the scientific treatment of this infirmity has been so long neglected and by the general body of the profession is so little understood, we must hail every addition to the literature which treats of aural disease as a positive boon. In Dr. Allen's "Lectures on Aural Catarrh," much useful knowledge expressed in a simple and intelligible manner is to be found. When the description and treatment of this one form of ear disease fills a volume of nearly three hundred pages without any superfluous matter being contained in it, the various affections of the aural structures would seem to occupy a wider range than has been hitherto conceded to them. Dr. Allen's book is both practical and clear, we cannot help considering he attaches too much importance to his method of inflating the tympanum; this was at one time largely practised both in England and on the Continent, but fell into disrepute among English practitioners, in consequence of one or more deaths occurring from its employment, in the practice of a London aurist, and of late years it has been employed more as a diagnostic than as a remedial agent. Nor can we consider the method which Dr. Allen proposes for forcibly rupturing the membrane of the tympanum by means of Politzer's bag, to be practicable in the condition of the parts which would alone render such an operation justifiable. If it becomes necessary to puncture this membrane either for the exit of fluid in the tympanum which cannot find egress through the natural channel of the Eustachian duct which is obliterated by inflammatory congestion or other causes, or in consequence of an hypertrophied condition of the membrana tympani, the usual and more simple method of performing this operation, is to be preferred to that which Dr. Allen suggests. Though compelled to differ with the author on these points, we can recommend this little work to the practitioner as a welcome addition to the subject of which it treats.

#### ST. GEORGE'S HOSPITAL REPORTS.

THE completion of a fifth volume of hospital reports\* by the staff of St. George's is worthy of special announcement, and although there is much to be said against such undertakings we naturally welcome a volume that contains so many original and practical essays. We shall take other opportunities of referring to those individually. At present we are only concerned to report that this volume is equal to its predecessors, and that it contains the following papers:

1. Jottings from Clinical Practice. By H. W. Fuller, M.D.
2. The Effects of Overwork and Strain on the Heart and great Blood-vessels. By T. Clifford Allbutt, M.D.
3. On Scarlet Fever. By E. Copeman, M.D.
4. Cases of Accidental Poisoning. By C. Paget Blake, M.D.
5. The Modern Treatment of Syphilis; based on the Evidence adduced before the Committee appointed to inquire into the Pathology and Treatment of the Venereal Diseases. By Edgecombe Venning.
6. On Scrofula. By J. Warrington Haward.
7. On Recurrent Insanity. By G. Fielding Blandford, M.D.
8. On Destrain of the Heart. By Reginald Thompson, M.D.
9. Labio-glossolaryngeal Paralysis. By W. B. Cheadle, M.D.
10. On the Etiology of Pneumonia. By Octavius Sturges, M.D.
11. On Ankylosis. By B. E. Rothurst.
12. Scarlet Fever as an Epidemic. By A. W. Barclay, M.D.
13. On the Relative Influence of Bread, Honey, and White Sugar upon the Amount of Urea and Sugar excreted in Diabetes. By W. Wadham, M.D.
14. On the Recent Outbreak of Small-pox at St. George's Hospital. By T. Jones, M.D.
15. Results of Recent Vaccination in St. George's Hospital. By R. Wilson.
16. Results of Recent Vaccination in the 1st Regiment of Life Guards. By Edgecombe Venning.

\* "Lectures on Aural Catarrh, or the Commonest Form of Deafness and their Cure." By Peter Allen, M.D., Aural Surgeon to St. Mary's Hospital, &c. London: J. and A. Churchill, 1871.

\* "St George's Hospital Reports," Vol. 5. Edited by John W. Ogle, M.D., F.R.C.P., and Timothy Holmes, F.R.C.S. London: John Churchill.

17. Annual Report of Medical Cases. By R. Thompson, M.D. 18. Annual Report of Surgical Cases. By W. Leigh. 19. Ophthalmic Report from December, 1868, to July, 1870. By H. Power. 20. Ophthalmic Report from August, 1870. By R. B. Carter. 21. Notes taken in a German Feld-Lazareth. By W. Ewart.

### A NEW BULLET EXTRACTOR.

THE shooting of Head-constable Talbot, and the difficulty experienced in finding the fragments of the bullet, have suggested the construction of a new instrument, or rather a modification of the electric probe, by which Dr. Evory Kennedy, of Dublin, hopes to make the detection and removal of the ball a matter of scientific certainty.

The electro probe, as our readers know, is formed of two wires, insulated from each other, and to each of which the opposite poles of a battery are attached. As long as the points of these wires are separated from each other the battery is quiescent, but the moment the ends touch the ball, and thus make metallic connexion, the battery rings a bell. Thus far the instrument is only applicable to the diagnosis of the bullet, but Dr. Kennedy hopes to make it efficient for extracting it also. The wires of the probe are made of platina, which, the instant the ball is touched, fuse by the heat evolved by the electricity into a solder with the lead, and becoming thus adherent, the ball may be removed without any second proceeding. The oxide of lead on the outside of the ball forms an obstacle to the passage of the electricity, but this difficulty is removed by tipping the points of the wires with nitrate of ammonia, which immediately dissolves the film of oxide, and produces a clean surface, suitable for the co-fusion of the metals. Dr. Kennedy is engaged in experiments with Mr. Yates for the perfecting of the instrument. We shall publish a full and descriptive illustration of the instrument when these experiments have concluded.

## Correspondence.

### SKIN GRAFTING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The enclosed letter, which I received from my son who is attending the military hospital at Bonn, though not written for publication, might perhaps interest some of your readers, and I therefore place it at your disposal if considered worth a place in the MEDICAL PRESS AND CIRCULAR.

Yours faithfully,

WILLIAM BARKER, Prof. Chem. R.C.S. Ireland.

I send you a short account of an experiment I have made here, not only because it may interest yourself, but also perhaps prove of interest to some of my former teachers in the Hospital and College of Surgeons, to whom I respectfully offer it for perusal, with the kindest remembrances.

Having been left during the absence of one of our surgeons in sole charge of some of the wounded who had suffered in a frightful way from hospital gangrene of the worst form, but who have all come safely through their illness, though still with wounds of great superficial extent, I thought I would try the transplantation experiment. The following is the simple way in which it was carried out: A slip of plaster was cut long enough to go round the limb. Having asked one of the surgeons who happened to come in, to take up a small fold of skin on my left arm with a forcep, I cut out with a sharp scalpel a piece of skin about the size of a large split pea

and laid it down on the surface of the cleaned wounded surface. Having pressed it slightly on the granulations, I laid over it a small piece of lint, on each side of which was also placed a strip of the same, in order that the plaster strip should not come in contact with the transplanted piece or on the granulations in its neighbourhood. The plaster was then fastened to a healthy part of the skin, passed over the lint and round the limb, which was a lower extremity, and of which the tibia for about three inches had been laid bare, besides which the skin, cellular tissue, and a portion of the muscle of the calf as far as the heel had been partially destroyed by this frightful affection.

Everything was left quiet during the dressing of the other parts of the wound for three days, and when the plaster was removed and the guarding middle square of lint carefully raised, the piece of skin was found lying with its epidermis close down on the granulations. Not being sure that it was not adhering only by the pus, I again dressed it as before, and left it undisturbed till next morning, when it appeared in its former position, from which it was not moved on letting a stream of water flow over it. The following morning it was apparently quite fixed in its place, but it was also smaller. It remained in this state for some days, but the granulations around the piece of skin, became finer and of a deeper red colour as may always be observed at the immediate edge of growing new skin. The professor of surgery, who had been told of this little affair, asked me, at his clinique at what hour I dressed the wound, and came to see if it had succeeded. He was quite satisfied it had done so, at least as far as the growing on of the transplanted skin was concerned, and it now remained to be seen if the epithelial cells of the epidermis would spread themselves out further from this little island, and accomplish the desired end of more rapidly covering the large suppurating surface with new skin.

But before going further, it would be well to compare this experiment with another which I made on the same morning, as it explains a difference which may occur, dependant on the different modes of manipulation. The piece of skin in this second case though larger than the first, did not unite rapidly, I should say in consequence of having as my assistant, only an hospital sergeant, who had to take the fold of skin in my arm with a forceps, and being afraid of hurting me, did not grasp the skin with sufficiently firmness, so when I had cut half through with the scalpel he let the piece go, and I had to take it up again and make a second cut. This interruption made the edges of the piece more irregular than in the first case; it was also thicker and therefore prevented the epidermis coming right down on the surrounding granulations when placed upon the cleaned wound. It was arranged as the former experiment, and after two days I took the dressing off and found the piece of skin adhering slightly to the lint. I tried to guard against this by putting some cerate on the next dressing, but this did not prevent the adhesion, and on the sixth day, the superficial layer came completely away as a scale leaving only a most minute portion of tissue behind. This probably contained the rete malpighi; and though not very sanguine as to the success of the trial, I dressed it carefully and awaited the result, hoping that even though the rete were destroyed, still a few epithelial cells might still remain, perhaps in the minute pores of the skin, glands, or round the hair bulbs, which would be capable of spreading. This minute portion became smaller and smaller daily, until it appeared as a mere atom of tissue in the midst of the granulations. I was surprised to hear on the eighteenth day (not having been for some days in the hospital), not only had the first transplanted portion on the legs become much larger, but that the transplanted portion in the second case was surrounded by new skin; and on dressing the cases I found that in the first case a new edge of skin had been formed about a quarter of an inch broad, forming a rapidly increasing island in the middle of the wound, and in the second case the transplanted portion had a considerable blue edge. Now, in these two cases, both commenced on the same day, and both completely successful in the opinion of the surgeons who saw them, there are yet points of difference which seem interesting, as touching on a point which has been doubted, whether epithelial cells can be formed from those belonging to other tissues without the presence of earlier formed epithelium cells. Judging from these two trials, at first sight, one might be led to think that such might be the case, for in the last-mentioned instance, the epidermis, and of course a certain portion of the underlying layer came completely away, and yet what remained became the centre of formation of new

skin; but then the other case, in which the epidermis lay close down on the granulations, from the very first, progressed much faster, acquiring very soon a blue line around it, and is now very much larger than the other, although the originally transplanted piece was smaller. Here we know that the epithelial cells came into actual contact with the fresh wound, and that it grew very much faster than the other where this was not the case. This certainly seems to favour the opinion that you must have formed cells of this peculiar kind before you can have new ones increased, else why should the smaller portion of the skin under the same circumstances have increased in size so much more rapidly than the other; of course it is no *proof*.

The idea that it is possible for epithelium to be formed out of the cells of other tissues arises from the fact that, it occasionally happens that in the centre of a large suppurating wound where there is apparently no vestige of the old skin remaining, after a time a small point of a different texture from the surrounding granulations shews itself and increases in size, until it becomes the centre of a gradually enlarging portion of new skin. Such a case is to be seen amongst the wounded in this hospital which I have been dressing; it was of a man who had a very good stump after amputation. The cicatrix was completely healed when he was attacked by hospital gangrene, which soon opened up the stump and caused an immense loss of substance; it was, however, got under by very active treatment, and the wound cleaned itself and granulated well over the whole surface. After a time, a small spot like a flake of curd was observed on one part of the granulating surface, and fearing that it was the commencement of a particular species of the same gangrene which we had before observed, this spot was treated with strong dressings. After a few days, however, seeing that it had a malignant appearance, this treatment was discontinued, when it appeared to dry speedily, and in a short time showed itself as an increasing scale of epidermis, which rapidly increased in extent. This case might possibly lead one to think that, owing to some peculiar stimulus it was possible for a transformation of a few cells of the granulating substance into epithelial cells to take place, and certainly if it had occurred in the centre of a wound caused by a large loss of skin and underlying tissue by the knife, where the depth of the wound made it impossible that any of the skin appendages could be left behind, as for instance in an amputation of the breast, it would not be unreasonable to suppose that this was the case; but in a case of ulceration, no matter how severe, it is always possible that one or two sweat-glands or hair bulbs may escape the destroying power, and these, though not visible amongst the red granulations, may on the wounds taking on a healthy action be the seeds of new skin, that is, the cells which line them.

The microscopic anatomy of the cells of epithelium, and their wide difference from those of other tissues, would also be a strong objection to the possibility of such a transformation. Then, comparing these two experiments again will show that it is not necessary to have actually the epidermis, for in one of the cases this came completely away, and yet the new skin spread itself out though far more slowly than in the case where the epidermis was immediately engrafted. Whether this took place from those cells lying over the papillae of the cutis vera, or those lining the sweat pores or hair follicles in its substance of course cannot be proved; as also whether it might not have been merely the stimulus of the new tissue causing the before mentioned transformation, but at all events, comparing the rapidity of this growth with that in which the true and mature epidermis commenced the action, the latter does not seem probable. In talking over this matter with the professor of surgery, he proposed an interesting modification, which he thought might succeed. It was that one should scrape some cells and tissue from the surface of the cutis vera, having previously removed the cuticle with a blister and plant this substance in the centre of the wound, covering it carefully. I mentioned to him also another modification of which I had been thinking, namely, to pull out some thick hairs of the body to the roots of which epithelial cells are clinging, and to plant these in the centre of the wound where possibly they might spread. This was done this morning by the surgeon whom I have been assisting, and who since his return has also transplanted a piece of skin with complete success. In conclusion, I feel satisfied that much has been won by this treatment, for not only is the wound healing from the edges, but also rapidly from the central transplanted portion, and thus the tedious process of cure is much shortened.

ARTHUR E. BARKER, L.R.C.S.I.

## Medical News.

**Royal College of Physicians of London.**—At an extraordinary meeting of the College on Monday, the 24th July, the following gentleman was duly admitted a *member* of the college:—

J. Burney Yeo, M.B., Lond., 68 St. James's street, S.W.

At an ordinary quarterly meeting on July 27th, the following gentlemen, having passed the required examinations were duly admitted as members:—

Carter, William, M.B. Lond., Elizabeth street, Liverpool.

Clarke, Jacob Augustus Lockhart, M.D. St. And., Warwick street.

Eastwood, Joseph Wm., M.D. Edin., Dinsdale park, Darlington.

Evans, George Henry, M.D. Camb., St. Thomas's Hospital.  
May, Emanuel, Bedford place, Russell square.

**Royal College of Surgeons of England.**—At meetings of the Court of Examiners on Tuesday, Wednesday, and Thursday, the following candidates passed the required examination for the diploma, and were admitted members of the college, viz.:—John Nelson Kiddle, Adelaide road, N.W.; Frank Edward Barrow, Woolwich common; Edward James Domville, Exeter; Edward George Younger, L.S.A., Blackheath hill; Henry Edward Southée, L.S.A., Ely, Cambridgeshire; Frederick Howard Clarke, L.S.A., Devonport, and Charles Haggitt Johnson, L.S.A., Hull, students of Guy's Hospital; Francis Edward Thurland, Thurstaston, Cheshire; Cleland Lammiman, Commercial road, E.; Charles Hutson, Barbadoes; Isidor Isaac Lyons, L.R.C.P., and L.M. Edin., and L.S.A. Lond., Alexandra road, St. John's wood, and Isaac Willcocks, L.S.A., West Looe, Cornwall, of St. Bartholomew's Hospital; Thomas Hughes Brabant, Chippenham; Clement Cuthbert Walter, Dover; Frederick Canton, Great Marlborough street, and Wallis McDonald, L.R.C.P. Edin., Teignmouth, Devon, of St. George's Hospital; Alfred Fletcher Holden, Cape of Good Hope; Edward Williams, L.S.A., Aberbank, Llandyssel; William George Watson, L.S.A., Sydney, Australia, and William Harris Heygate, L.S.A., West Haddon, Northamptonshire, of University College; Robert Eardley-Wilmot, Chandos street, W.; Francis Henry Spencer, L.S.A., Chippenham, and Samuel Wickes Fitt, L.R.C.P. Edin., Trinidad, West Indies, of King's College; Robert Strickland Hannay, Belfast; Gilbert Smith, B.A., Dublin, Blackrock, County Dublin, and Robert Bath Wybrants, L.K. and Q.C.P., Ireland, Shepton Mallet, of the Dublin School; Robert William Edginton, Stow-on-the-Wold, and Frederick Fraser Hopkins, Henley-in-Arden, of the Birmingham School; Evan Thomas Hughes, L.R.C.P. Edin., and L.S.A. Lond., Tynrallt, Anglesea, and Joseph Thompson, L.R.C.P. Edin., Kirby Stephen, Westmoreland, of the Glasgow School; John Butler Edis, Peterborough, and William Curling, L.R.C.P. Lond., Ramsgate, of the London Hospital; William Edward Leoyard, M.B. Toronto, Toronto, Canada, of St. Thomas's Hospital; Hugh Robert Greig Hughes, Bangor, North Wales, of the Edinburgh School; Stephen Foulton Conolly, Kilburn, N.W., of the Charing-cross hospital; and Francis Charles Bryan, L.S.A., Northampton, of St. Thomas's Hospital; Charles Read, of Guildford place, London; Ashwin Conway Newman, L.S.A., of Cheltenham; Charles W. Pratt, of Plymouth; Thomas Rowing Fendick, of Mylne street, London; John C. Clarke, of Coleraine, Ireland; Rutherford John Pye-Smith, of Hackney; John Scully, of Wimpole street, London; Joseph Clement Norman, of Colchester; George C. Briggs, L.S.A., of Horncastle, Lincolnshire; Edward S. Bishop, of Manchester; William Hugman, of Guildford street, London; Bentham Paynton Morison, L.S.A., of Pembroke, South Wales; William Garton, of St. Helen's, Lancashire; Charles C. Rogers, of Cork street, London; James Reed, L.S.A., of Stoke, Devonport; George E. Cheyne, of Thornton heath, near Croydon; Henry Arthur Latimer, L.S.A., of Plymouth; Ernest A. Elkington, of Birmingham; Henry J. W. Barrow, of Nightingale terrace, Woolwich; William Appleton Meredith, of Wimpole street, Cavendish square; Arthur R. Saunders, of Haverfordwest, Pembrokeshire; George Frederick Slack, of Montreal, Canada; Albert Barnes Rees, of Swansea, South Wales; James Godfrey Thrupp, of the Marylebone road; Frederick Aubin Monks, L.S.A., of Hoxton, N.; Charles H. Hill, of Teddington, Middlesex; Thomas Vaughan Aylen,

L.S.A., of Southsea, Hants; George Arthur Phillips, L.S.A., of Whitwell, Hertfordshire; Edward Rice Morgan, of Swansea, South Wales; John Peplow Cartwright, of Oswestry, Salop; William Lane Marley, of Padstow, Cornwall; George S. Payne, of Hartfield, near Tunbridge Wells; Thomas Mayne, of Stonehouse, Devon; Michael Sweeney M'Donnell, of Glasgow; David A. Davies, of Swansea, South Wales; John Storrs Brookfield, B.M., and M.C., Edinburgh, of Halifax, Nova Scotia; William Francis Hazel, L.S.A., of Oakley square, N.W.; Marcus Henry Allen, of Brighton; and Clement Hadley, of Birmingham. Sixteen other candidates were examined, but were not approved.

**Public Health and Local Government.**—Sir C. Adderley, in moving for leave to bring in a bill to consolidate and amend the laws relating to public health and local government, said the bill, which was intended to apply exclusively to England and Wales, was founded upon the report of the Sanitary Commission appointed a couple of years ago. The House would be able to judge of the heterogeneous character of the existing sanitary laws from the fact that forty Acts were reduced to one in the bill he asked leave to introduce. The sanitary Acts had been multiplied to such an extent during the last twenty-five years that the law was reduced to absolute inanition, and one of the results of that chaotic mass of legislation was to multiply local authorities and increase expense. Another object of the bill was to put an end to the optional state of things which existed, and to apply the law to every part of the kingdom, so that it should be universal and uniform throughout. No new authorities and no new expenses would be created under the bill. On the contrary, it would diminish the number of offices and officers, and curtail expenditure. The bill would not interfere with the local Acts of the large towns. Another object of the bill was to simplify areas which in many instances at present overlapped each other. With reference to the bill introduced by the President of the Poor-law Board, he was surprised by the opposition which was given to it, for without a central authority it would be impossible to provide adequately for the administration of the law. The object of the central authority was not to take the work out of the hands of the local authorities, but to set them in motion. There were thousands dying annually in this country from preventable causes. The bill contained 450 clauses, but nine-tenths of it consisted of re-enactments. Under its provisions the whole country would be mapped out into sanitary districts—an arrangement which had already been carried into effect in Hampshire, chiefly owing to the exertions of Lord Eversley and other magistrates. If the House should grant him leave to introduce the bill, he did not mean to press it further in the present session; but he expected when the country became aware of the benefits it would confer, that a strong demand would be made to have it passed into law in the next session.

**A Liverpool Surgeon Charged with attempted Murder.**—At the Liverpool Police court on Friday week, Mr. J. Martin, a surgeon, practising in St. James's road, Liverpool, was brought up on remand, before Mr. Raffles, on a charge of attempting to murder Catherine M'Hale, a domestic employed in his house, by cutting her throat. The prisoner had been remanded, in order that he might be examined by two physicians as to the state of his mind. A certificate from these gentlemen was put in, in which they stated that it would be unsafe for the accused to be at large. Mr. Raffles considered that the prisoner, who was a most violent and dangerous man when under the influence of drink, should be bound over in two sureties of £100 each, to keep the peace and be of good behaviour for six months.

**The German Losses by Sickness in the War.**—The *Volkstaat* observes that there is an unwillingness in influential circles to allow the full extent of the German losses in the late war to transpire. The list of killed and wounded was made public, as it could not be avoided, although in a very inaccurate and incomplete manner. On the other hand, there has been a determined objection to giving statements of figures with regard to the devastation brought about by sickness. Vague forms of speech were reckoned satisfactory, and it was boldly asserted on several occasions that the health of the army was excellent, "better than in times of peace," although the endless convoys of sick, as well as thousands of soldiers' letters, gave the lie to such statements. A semi-official corroboration now suddenly appears of the worst rumours which were circulated in process of time. The Central Bureau of Information in Berlin, under the inspection of the highest military authorities, has published a report of its work, with

interesting statistical figures. It appears from this report that the institution has, within the space of twelve months, authenticated 633,000 sick and wounded cases, and that of these only 73,000 belonged to the French, the remaining 555,000 to the German army. The circumstance that only 46,000 of these were South Germans, and that nearly 508,000 were North Germans, shows by the disproportion of the numbers that the Bureau had really been occupied with the North German army. The frightful figures, which besides make no claim to completeness, are, according to this, far below the truth. And if we reckon the wounded at a hundred thousand in round numbers, we shall certainly still be within the truth if we estimate the number of the unwounded sick at half a million. How many of these have died, or drag about an incurable body, is more than we can say, failing the necessary information. The figure must, however, be a terrible one.

## Gleanings.

### High-heeled Boots, Chinese Feet, and Crooked Shins.

It is worthy of note that while a malignant hatred of Chinese, individually, is fomented under cover of hostility to their immigration, our females have fallen in love with Chinese costumes and customs, in some respects, and accepted them as models. The pictures of Chinese ladies, to which one has been accustomed for many years, bear a close resemblance to the American belle of the present day. The repulsive hump, the crippled feet, and the mincing gait of our women, if they do not fortify the Darwinian theory of the origin of the species from monkeys, at least give the appearance of retrograding monkey-wards. The dress, uncouth and deforming as it is, would not of itself deserve notice; but the high heels, crippling the feet and distorting the limbs, are an outrage on grace, on anatomy, on humanity, entitling the authors, could they be detected, to criminal responsibility. A convention of corn-doctors, in the interest of their trade, could not devise a better scheme for good times. Women whose pedals are solidified, may escape with only corns, of which we hope and pray they may have a full and tender crop. But that a whole generation of little girls should have their toes jammed into the points of their boots, to do the work of heels, and that their legs should be thrown out of the natural balance, and the pliant bones bent into semicircles, is a sacrifice to fashion which would disgrace a nation of Hottentots. Should the wicked custom hold a few years, there will not be a decent foot or an esthetic leg in our female population, except among washerwomen and the like. And all this is a trifle compared with the mischief done to the pelvis, spine, and chest, by the constrained attitude with the abnormal elevation of the heel must of necessity induce. Fashion is at best a cruel tyrant; but the whole history of her capricious rule does not exhibit a grosser violation of natural laws, and a more unpardonable assault on the beauty and health of woman, than the invention of HIGH-HEELED BOOTS.—*Pacific Medical and Surgical Journal*.

### Write your Prescriptions in Plain English.

THE best commentary we have seen on the popular outcry against the use of Latin, or scientific names for medicines, is contained in a current newspaper article, attributing extraordinary virtues to the *hydrastis canadensis* as a cure for small-pox. As to the plant, it is probably as good as the *sarracenia*. But the point of the article is the statement that "the plant is popularly called orange root, and sometimes yellow puceon, but it must not be confounded with another plant commonly called puceon."—*Pacific Medical and Surgical Journal*.

### Ergotin Subcutaneously in Metrorrhagia.

IN the *Presse Med.*, 46, 1870, there is the report of a case in which the bleeding, whose cause was obscure, had continued for two months, being occasionally checked for a few hours at a time, by cold injections, and ergot internally. Ergotin to the amount of 0.12 grm., dissolved in a mixture of glycerine and distilled water was injected subcutaneously, and less than four hours after the discharge ceased. As a measure of precaution, the injections were repeated on the three following days, and there was no return of the hæmorrhage.

### Medical Properties of the Leaves of the Blue Gum.

DR. F. W. LORINSER (*Wiener Med. Wochenschr.*, 27, 1870) prepared a tincture with 1 part of chopped fresh leaves, to 3 of rectified spirit. He gave this in doses of a teaspoonful, morning and evening, to two patients suffering from pyæmia and tuberculosis, in whom febrile attacks recurred regularly. The attacks on the next fever day were less severe, and on the following one they did not appear at all. A relapse after six or eight days was removed by the same means. Encouraged by these results, he requested physicians practising in ague districts to make a trial of the tincture. The cases reported amounted to 53, and of these 43 were completely cured, and in 5 cases of relapse, quinine had to be given on account of the supply of tincture failing. Only in one case did the medicine after sufficient trial show itself powerless; but quinine had also been given without effect. In 11 of the 53 cases quinine had been used without advantage, and in 9 of these, the tincture effected a complete cure.

According to Paul and Gubler (*Gaz. de Paris*, 20, 1870,) the powdered leaves of the *Eucalyptus Globulus* are useful in bronchitis.

### Action and Uses of Extract of Meat.

REFERENCE has already been made in these notes to the researches of Kemmerich on this subject. He makes a further contribution in *Deutsche Klinik*, 16, 17, 1870. After administering the extract in the form of soup to animals, he found the mucous membrane of the stomach in a state of active hyperæmia, and especially at those places where the glands secreting the gastric juice are situated. It is to be assumed, therefore, that the use of the meat extract favours secretion of the gastric juice. He found that, under the moderate use of the extract, the pulse is quickened and becomes stronger, and that there is at least a temporary increase in the temperature. Too large quantities are injurious, especially to young and weakly persons, and for adults, the average amounts should be only about five grammes in the day, and should never exceed fifteen. When given along with suitable food, to persons recovering from exhausting diseases, the increase of weight is more rapid, and the period of convalescence materially shortened. As a stimulant, it resembles alcohol and coffee, but has the advantage over them of aiding in building up the structures of the body.

### Chloroform.

CHLOROFORM, the most important of all anæsthetics, was discovered first by M. Soubeiran, in 1831; then by Baron Justus Von Liebig; and its chemical and physiological properties were more fully investigated by Dumas, in 1835. It is formed chlorine acting on marsh-gas, and is prepared on the large scale by distilling together bleaching powder (chloride of lime) containing a little quicklime to render it alkaline, water, and spirits of wine, or wood spirit; the distilled liquor is then shaken with several successive portions of distilled water to free it from any soluble impurities, agitated with its own weight of pure oil of vitriol, and lastly, distilled from a mixture of chloride of calcium and quicklime, which removes every trace of water and acid, and renders it much more permanent and safe to use than if these impurities were allowed to remain. The specific gravity of pure chloroform is variously given at 1.497, 1.500, and 1.525; the last density, however, is too high, as the chloroform of the best makers is generally 1.497 or 1.500. It is a dense mobile liquid, having a pleasant ethereal odour and a warm, sweet taste; exposed to the air it rapidly volatilises, leaving no residue; it boils at 141 deg. F., and is not easily made to catch fire, but when it burns it does so with a dull, smoky, greenish flame. Chloroform vapour is rapidly absorbed by the atmosphere, and this capacity of absorption varies with the temperature, having a certain definite maximum for each degree; for instance, it is found that air at 40 deg. F. will take up 6 per cent. of vapour, while air at 98 deg. F. is capable of taking up 35 per cent. Chloroform is also the best known solvent for camphor, resins, sealing-wax, and gutta-percha, it also dissolves the vegetable alkaloids, strychnia, morphia, quinia, &c., in large proportions, and is very useful as a local anæsthetic in allaying the pain of tooth-ache; as a solvent it will remove greasy spots from fabrics of all kinds, but its chief use is as an anæsthetic, of which kind of medicinal agents it is the type. There are several other volatile organic bodies which possess similar properties, but none, so far as we have yet been able to discover, produce the total unconsciousness, and muscular relaxation, that follow the inhalation of chloroform.—*The Mechanic's Magazine*.

### NOTICES TO CORRESPONDENTS.

IS CHOLERA COMING?—Many alarming statements have been made on this question, and no harm can result at any amount of precaution taken. Still we hope we may be spared the infliction, and there are many reasons for hoping this may be so. Cases have, however, occurred nearer than before, and we have given full accounts of its progress in Russia. The *Globe* of Monday, says that cholera has not broken out at Hull yet, neither in the town nor amongst the shipping, but it has made its appearance at the Baltic ports in ships that run between this country and those ports; and what is not pleasant to hear, a death—if not more than one—has occurred in a ship soon after leaving Cronstadt, and when on its way to Hull. The next thing may be the appearance of cholera amongst some of the sailors actually in the port of Hull. Let us hope not.

DR. EWING WHITTLE, Liverpool.—Communication "On the Population Question," received as we were going to press. We wish it to be distinctly understood that, because in the discussion upon "The Population Question," we admitted the views of "the Malthusian School," we did so simply in accordance with our established usage of giving *both sides, and not* because they were an exposition of our principles in the matter. Our esteemed contributor must therefore not infer that we are disciples of that school, as with its doctrines *generally* we totally disagree. It can scarcely be conceived that so scientific a man as its founder could propound a theory so absolutely rotten, as not to contain "one jot or tittle" of good, and this, however small, we hoped would be eliminated by the free discussion of medical and scientific men in the columns of a medical journal. That it has had this effect, we are impressed by the congratulatory letters received from so many of our readers. On the other hand, the subject gave offence to a few of our friends for various reasons, chiefly on account of the extraneous and irrelevant matter introduced. This, of course, will always happen. We have refused insertion to a large number of letters, on the grounds that we could not find space to prolong a discussion which only repeated itself in each letter, without affording anything new. Last week we refused one whose views are opposed to those of Dr. Whittle, the notice of which will be found in our last number, page 87. If, therefore, for the same reason, we are reluctantly compelled to decline his communication, Dr. Whittle must kindly not impute it to "our partiality for the Malthusian Doctrine," which we certainly cannot acknowledge.

MR. THOS. TURNER, F.R.C.S.—Many thanks. Request shall be attended to.

MR. ANNESLEY LAMR.—We were uninformed of the arrangement.

MR. H. H. COX.—Received late, but shall be attended to.

F. A. H.—Mr. Hardwick, Piccadilly.

MR. HARRISON.—The book is very popular in America. You probably would be able to get it in this country from one of the foreign publishers. Baillière, Trübner, or Nutt.

HILL RESIDENCES FOR EUROPEANS IN INDIA.—We have been favoured with a most elaborate article upon this subject, from the pen of Dr. W. Curran, of Her Majesty's Army Medical Staff. The tabular matter has been compiled with great care and exactness, and we much regret that its length—thirty columns—bars its acceptance for our pages. If the author will kindly reduce it, we shall be pleased to accord space.

The following communications are in type, and will appear, if possible, in our next:

Dr. Lombe Atthill, "On Diseases peculiar to Women." Lecture VII. With Illustration on Toned paper.

W. E. Teevan, B.A., F.R.C.S., "Case of Retention of Urine from Impassable Stricture, treated by Filiform Bougies."

G. Smith Chartres, M.A., M.D., "Syphilitic Iritis attacking both Eyes in succession, treated principally by Oil of Turpentine and Blisters."

### VACANCIES.

Middlesex Hospital. Physician. Honorary.  
University of Durham. Medical Tutor. Salary £120 per annum.  
Edinburgh Veterinary College. The Chairs of Zootomy, or Comparative Anatomy, and of Cattle Pathology.

Wandsworth Board of Health. Two Medical Officers. Salary £50 each.

Bridgewater Union. Medical Officer. Salary £36, with midwifery fees.

Plymouth. Medical Officer for the Northern District. Salary £96.  
Her Majesty's Naval Hospitals. Assistant Dispensers in charge of Medical Stores. (See advt.)

### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

An Experimental Research on the Antagonism between the Actions of Physostigma and Atropia. By Thos. R. Fraser, M.D.  
Puerperal Temperatures. By William Squire, L.R.C.P. London: Churchill.

Hospital Statistics. By Chas. Kemble, M.A., Bath.  
Poisoning and Pilfering, Wholesale and Retail. London: Longmans.  
Australian Medical Gazette; Canada Lancet; Woodhull's Weekly.

### APPOINTMENTS.

BARBER, W. L., L.R.C.P.L., M.R.C.S.E., Assistant Medical Officer to the Portland Convict Prison.

BROWN, Mr. J., Assistant Medical Officer to the Leeds General Infirmary.

CATON, R. M.D., Demonstrator of Practical Physiology and Histology at the Liverpool Royal Infirmary School of Medicine.

CONNOR, S. J., L.K.Q.C.P.L., Medical Officer to the Carlow Fever Infirmary.

DOVE, W. W., L.R.C.P.Ed., Assistant Medical Officer to the Somersetshire Lunatic Asylum, Wells.

FRIER, WILLIAM, M.D., M.Ch.Q.U.I., Medical Officer to the Warings-town Dispensary District, Lurgan Union.

JANSDOWN, F. P., re-elected Surgeon to the Bristol General Hospital.  
M'CRAITH, E., L.R.C.P.Ed., L.R.C.S.Ed., Medical Attendant to the Royal Irish Constabulary, Michelstown, Co. Cork.

RISDON, A., Second Resident House-Physician to St. George's Hospital.

SCOTT, W. G., M.B., House-Surgeon to the Blackburn Infirmary.  
STOCKER, J. R., M.B., Medical Tutor and Pathologist at St. Mary's Hospital Medical School.

**TURNER, J. S., M.R.C.S.E., L.S.D.,** Lecturer on Mechanical Dentistry at the London School of Dental Surgery.  
**DICKSON, J. THOMPSON, M.A., M.B., M.R.C.P.** has been elected a Physician to the Infirmary for Epilepsy and Paralysis, Charles street, Portman square, London, W.

**Marriages.**

**ELLEY-CLARK.**—On the 20th ult., at Plympton St. Mary, Devon, R. Elley, L.R.C.P., M.R.C.S., of Ridgway, Plympton, to Elizabeth Mary, daughter of J. E. Clark Esq., of Underwood, Plympton, Devon.  
**GOYDER-THOMAS.**—On the 20th ult., at St. Mary's, Moseley, near Birmingham, David Goyder, M.D., of Bradford, to Anna Eliza, daughter of Robt. Thomas, Surgeon, of Bradford, near Leeds.  
**POOLEY-WRIGHT.**—On the 18th ult., at St. James's Church, Mason Pooley, Medical Officer of Rochdale Infirmary, to Charlotte Louisa, youngest daughter of Joseph Wright, Esq., of Eden-vale, Dublin.

**Deaths.**

**CLARKE.**—On the 21st ult., at Shallowfield House, Norton-bridge, William Clarke, Surgeon, aged 59.  
**COURTNEY.**—On the 16th ult., at Haslar (from blood-poisoning in dressing a wound), Charles F. A. Courtney, Surgeon R.N.  
**ROSS.**—On the 19th ult., at Upper Lewes road, Brighton, W. H. B. Ross, L.R.C.S.Ed., Surgeon-Major Bengal Army (retired list), aged 55.  
**SHIRLEY.**—On the 25th ult., at Grove terrace, Highgate road, Henry James Shirley, F.R.C.S., late Surgeon Worcester Militia, aged 52.

**Advertisements.**

**APOTHECARIES' HALL, BLACKFRIARS.—**

The next EXAMINATION in ARTS will be held at the HALL on FRIDAY and SATURDAY, the 29th and 30th SEPTEMBER, 1871. A Syllabus of the Subjects for Examination may be had on application.

An Examination in ARTS will again be held in the month of JANUARY, 1872.

R. H. ROBERTSON, Secretary to the Board.

**PRIZES IN MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.**—The next Examination for the Society of Apothecaries' Annual Distribution of Prizes in Materia Medica and Pharmaceutical Chemistry will be held at the Hall of the Society, on Wednesday the 18th and Friday the 20th of October, at 10 A.M. The Prizes consist of a Gold Medal and a Silver Medal and a Book. Gentlemen intending to compete for these Prizes must send a written notice of their intention to the Beadle, before the 7th day of October, which notice must be accompanied by evidence of their being in attendance on the Third Winter Session of their Medical Studies.

By order of the Court of Assistants,

R. B. UPTON, Clerk to the Society.

Apothecaries' Hall, London, August, 1871.

**ST. THOMAS'S HOSPITAL MEDICAL and SURGICAL COLLEGE.**—The ACADEMICAL SESSION for 1871 and 1872 will commence on Monday, the 2nd of October, in the new buildings on the Albert Embankment, Westminster bridge, when Mr. F. Le Gros Clark will give the Inaugural Address.

MEDICAL OFFICERS and LECTURERS:—

Honorary Consulting Physicians—Dr. Barker and Dr. Bennett.

|                      |                |                       |
|----------------------|----------------|-----------------------|
| Dr. Peacock          | Mr. Croft      | Mr. Mason             |
| Dr. Bristowe         | Mr. Liebreich  | Mr. Arnott            |
| Dr. Clapton          | Dr. Stone      | Dr. Bernays           |
| Dr. Murchison        | Dr. Ord        | Dr. J. Wale Hicks     |
| Dr. Barnes           | Dr. Harley     | Dr. Wm. Rhys Williams |
| Mr. F. Le Gros Clark | Dr. Payne      | Mr. J. W. Elliott     |
| Mr. Simon            | Dr. Gervis     | Mr. Rainey            |
| Mr. Sydney Jones     | Mr. Mac Cormac | Mr. W. W. Wagstaffe   |

For entrances or prospectuses and for information relating to prizes and all other matters apply to Mr. Whitfield, Medical Secretary, the Manor-house, St. Thomas's Hospital, Newington, Surrey, S. E.

**PUBLIC SCHOOL EDUCATION IN IRELAND.**

**COLLEGE OF ST. COLUMBIA, RATHFARNHAM, COUNTY DUBLIN.**

VISITOR—THE LORD PRIMATE.

The College is intended for the Education of Boys from the age of nine years and upwards. The Course of Instruction is of the same nature as that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics, English, French, German, Drawing, and Vocal Music. Boys are prepared for the Universities of Dublin, Oxford, and Cambridge, or for the Military and Civil Service. Terms for Boarders—Sixty Guineas. A limited number of Sons of Clergymen can be received at Forty Guineas. There are two Exhibitions attached to the School, tenable at the University of Dublin, value not less than £20 a year. Lists of the School, and of recent honours gained by former pupils, together with all other particulars, may be had on application to the Rev. ROBERT RICE, M.A., of Christ Church, Oxford, Warden; or at Messrs. HONGES, FOSTER, & Co.'s, Publishers to the University, 101 Grafton street, Dublin. The Summer Vacation ends on August 16.

ESTABLISHED 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE  
 50 Lincoln's-inn fields, W.C.

**J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c.,** (KING'S COLL.), and Author of VIA MEDICA, has always upon his books a large number of desirable investments and available Appointments for negotiation. Gentlemen wishing to relinquish practice can be introduced without delay to suitable successors with means at their disposal.

Dr. Langley devotes his prompt personal attention to the negotiations entrusted to him, which are treated with the most scrupulous reserve.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

Dr. Langley can refer to many of the leading Members of the learned Professions in town and country as a guarantee of his integrity and honour in all matters of business entrusted to him.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**LOCUM TENENS.**—Dr. Langley has now organised a thoroughly reliable Staff of Suitable Gentlemen to take full Charge of any Practice which may require it in the absence of the principal, at fees from £2 2s. upwards, according to age, experience, qualifications, &c. One of these Gentlemen can be despatched by an early train after receipt of telegram or letter stating duties and terms. Office fee 10s. 6d. payable by the principal.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on receipt of two stamps) as below:—

- Y 251. **CONTINENTAL.** A doubly-qualified physician can be introduced to a first-class connection amongst English residents in a large and beautiful city of southern Europe. The connection is non-dispensing. There is a little midwifery at high fees. The introduction secures the best society, and is only suitable for a gentleman accustomed to move in the higher circles. The actual receipts have been £300 a year. But the number of English residents is increasing, and a considerable addition to the income might be secured. The furniture may be taken at a valuation if desired.
- Y 252. **PHYSICIAN'S PRACTICE** in a large county town. Income £900 a year. Working expenses very light. Patients of a good class. From a suitable gentleman a moderate premium will be accepted.
- Y 255. **ENGLISH PRACTICE** in an eastern city, where there are about 2,000 European residents, and frequent additions from tourists and others. The climate during seven months of the year is splendid, bright and cool. The practice realises £300 a year, and there are public appointments associated with it which bring in £240 a year. The expenses are light, no horse or carriage been required. The highest references can be given at home or abroad.
- Y 250. **LONDON SUBURBS.** A small but increasing practice, affording a good introduction to the district. Receipts, £300 a year; public appointments, £150. There is a convenient residence, with stabling, coach house, and half an acre of ground, rent £55. The house is situated in an open thoroughfare about 3 miles from Charing Cross. The furniture may be taken at valuation.
- Y 248. **UNITED STATES.**—In a large and improving city with a temperate climate and great municipal advantages a PARTNERSHIP with succession for transfer. Receipts average about £2,000 a year. Two valuable appointments to public works are held by the incumbent. Highest references can be given and moderate terms accepted from a doubly qualified British surgeon.
- Y 247. **KENT.** In a pleasant little town where there is no qualified opposition an old established PRACTICE realising about £450 a year, with little exertion, appointments yield £150 a year. The residence is a well-built house containing ten rooms with large gardens, meadows, stabling, coach house, &c. Rent £35. Midwifery fees, £1 1s. and upwards. One horse is employed. No assistant required and living very cheap. A complete introduction can be given to a suitable gentleman; time would be allowed for payment of part of the premium.
- Y 246. **LONDON.** Cash practice of £1,200 a year. An active PARTNER is required with £800 at his command. The books are open to the most rigid scrutiny and a personal experience of the practice can be allowed under suitable conditions. There are no bad debts. The principal attends no midwifery under £1 1s. The incoming partner may rely upon a clear income of £500 a year after payment of all expenses.
- Y 232. **LONDON.**—A large and old established PRACTICE for Transfer, under conditions affording the highest guarantees of good faith, as the vendor is retiring in consequence of serious and sudden illness. The books show that upwards of £435 were taken in ready money fees during last year, and that more than £700 were booked; the previous years show a much higher average, and very few bad debts. Midwifery fees at £1 1s. and upwards, yielded £140. Public appointments in a principal thoroughfare, with garden at the back, and stabling. Rent £80 a year. The residence is extremely convenient, situated in a principal thoroughfare, with garden at the back, and stabling. Rent £80 a year. There is a detached Surgery, where the Assistant resides. The introduction to the Practice may be by Partnership or otherwise.

**Dr. Langley's Quarterly List of Selecting PRACTICES and PARTNERSHIPS for JULY** is now ready. Post Free on application.

**VIA MEDICA:** a Treatise on the Laws a Custom of the Medical Profession, in relation (especially to Principal and Assistants. By J. BAXTER LANGLEY. 8s.

## The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

## GLENFIELD STARCH.

EXCLUSIVELY USED IN THE ROYAL LAUNDRY.

And Her Majesty's Laundress says that it is

THE FINEST STARCH SHE EVER USED,

Awarded PRIZE MEDAL for its Superiority.

When you ask for

### GLENFIELD STARCH,

See that you get it, as Inferior kinds are often substituted, WOTHERSPOON and CO., Glasgow and London

T. and H. SMITH'S

### CODEIA LOZENGES.

THESE LOZENGES have a remarkable effect in allaying Cough and Irritation of the Throat and Chest.

Prepared only by T. and H. SMITH and CO., 21 Duke street, Edinburgh and 12 Worship street, London; and to be had of any Chemist and Druggist, in Boxes at 1s. 1½d. and 2s. 9d. each.

### JAMES'S FEVER POWDER.

4s. 6d. PER BOTTLE, PACKETS 2s. 9d. EACH.

PREPARED and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remarks on the part of the Proprietor unnecessary.

To be had of all Wholesale Druggists

### FOR Varicose Veins and Weakness

**SURGICAL ELASTIC STOCKINGS** and **KNEE-CAPS**, pervious, light in texture, and **INEXPENSIVE**, yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise, a strong low-priced article for Hospitals and the Working Classes.

**ABDOMINAL SUPPORTING BELTS**, those for Ladies' use, before and after accouchment, are admirably adapted for giving adequate support with **EXTREME LIGHTNESS**—a point hitherto little attended to.

Instructions for measurement and prices on application, and the articles sent by post from the Manufacturers,

**POPE and PLANTE,**

WATERLOW-PLACE, PALL-MALL, LONDON.

The Profession, Trade, and Hospitals Supplied

### SYR. QUINÆ FERRIQUE SUPERPHOSPH. ET STRYCHNINÆ PHOSPH.

Is best Preserved without change at 60° Fahrenheit.

Each fluid drachm contains one grain of Quinine, two grains of Iron, and the 32nd part of a grain of Strychnine.

*Curtis & Co's*

Manufacturers of Pharmaceutical Preparations,  
48 BAKER STREET, LONDON, W.

### CHURCH STRETTON PRIVATE ASYLUMS

FOR THE UPPER and MIDDLE CLASSES of BOTH SEXES, are situated among the Shropshire Hills, Twelve Miles from Shrewsbury, on the rail to Hereford.

Apply to { Wm. HYSLOP Esq., Stretton House, for Gentle- } Church  
men; } Stretton, Shropshire.  
{ Mrs. BAKEWELL, the Grove, for Ladies. }

Vide page 1016 in the Medical Directories for 1871.

## PURE AERATED WATERS.

ELLIS'S

RUTHIN WATERS,

Soda, Potass, Seltzer, Lemonade,  
Lithia, and for GOUT, Lithia,  
and Potass.

CORKS BRANDED "R. ELLIS & SON, RUTHIN" and every avel bears their trade mark. Sold everywhere, and Wholesale of R. ELLIS & SON, Ruthin, North Wales. London Agents:—W. Best & Sons, Henrietta street, Cavendish square.

## PURE EXTRACT OF MALT.

Its use has been accompanied with decided benefit in ASPIRMA, BRONCHITIS, CONSUMPTION, ATROPHY, INDIGESTION, and in STOMACH COUGHS.

The analysis by Dr. ARJON states that the most remarkable of its constituents are those which include Nitrogen, the amount of which is unusually large—reaching as it does nearly 5 per cent. The Proteinic compounds in an ounce of it weigh 22.32 grains, and the analogous compounds in an ounce of beef-steak 98.43 grains. Hence weight for weight, the alimentary value of the Extract is very nearly one-quarter that of the beef-steak. It is, therefore, nutritious in a high degree, and being no doubt easy of assimilation, it must constitute an useful supplementary food in cases of debility and weak digestion.

To John Evans, Esq., M.D.

49 DAWSON STREET, DUBLIN.

## KOUMISS

The best Tonic and Blood-restorer, of the highest Nutritive power. Recommended in Consumption, Bronchitis, Debility, &c. Qrts., 18s.; Pints 10s. per doz.—Sold by the Sole Manufacturer, E. CHAPMAN, 10 Duke st., Portland place, London; and all Chemists and Druggists.

Dr. Jagielski's Book on Koumiss, post free, 1s. 1d.

## CLEAR COMPLEXIONS

for all who use the "United Service" Soap Tablet, which also impart a delicious fragrance.

MANUFACTURED BY

J. C. AND J. FIELD, Patentees of the Self-fitting Candles Sold by Chemists, Oil and Italian Warehousemen and others.

\* \* \* Use no other. See name on each tablet.

# TENAX

(Trade Mark.)

ABSORBENT AND ANTISEPTIC.

Specially prepared for Surgical purposes, and superseding Lint, Tow, Cotton Wool, and Oakum for Dressings.

"It possesses that tarry fragrance which is pleasant to patients; it is a cheap and simple kind of antiseptic dressing, capable of being applied to numerous surgical purposes, and is well worthy of the attention of medical men engaged in hospital or private practice. We may safely recommend it, as it has answered admirably in the cases in which we have applied it."—*Lancet*.

SOUTHALL, SON, and DYMOND, Manufacturing Pharmaceutical Chemists, Birmingham. Agents in Ireland: THE APOTHECARIES-HALL of IRELAND, Mary street, Dublin. TENAX may also be obtained from Retail Chemists, or any Wholesale Druggist in the United Kingdom.

**SALMON'S OBSTETRIC BINDER,** for immediate use after delivery, 5s. 6d., and 6s. 6d.

SALMON'S ELASTIC ABDOMINAL BELT affords the most effectual support during and after Pregnancy, and in cases of Prolapsus Uteri, Obesity, &c., of any hitherto made, as it more completely supports the lower part of the abdomen. Price 17s. to 50s.

Mrs. Salmon attends upon Ladies.

HENRY R. SALMON, 87, Wimpole-st., Cavendish-sq., London, W (Removed from 32, Wigmore-street.)

### CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE VII.

*Polypus—Varieties of—Cystic—Mucous—Fibrous—Symptoms—Intra-uterine, operation for removal of—Steel wire, advantages of—Modification of Gooch's canule—Fibrinous and placental polyp.*

IN the preceding lecture I have spoken of those forms of menorrhagia which depend on, or are caused by, an abnormal or diseased condition of the uterus or of its lining membrane; to-day I have to call your attention to an affection as important as any of the preceding, one too of frequent occurrence and which almost invariably gives origin to profuse menstruation. I allude to polypus, which may be defined as an affection the result of hypertrophy of some portion of the uterine substance, which taking the form of an out-growth becomes in time a distinct tumour, attached to the wall of the uterus either by a base of considerable extent, or more frequently by a well defined pedicle. These growths are met with of all sizes and shapes, sometimes as little stunted bodies only the size of a pea or small bean, sometimes as large tumours occupying the entire cavity of a uterus as large as that organ should be at the fourth or fifth month of pregnancy; but more commonly they are seen of intermediate size. Occasionally the uterus seems to resent the presence of a polypus which has been developed with-

in its cavity, and by contractions similar to those of labour expels it, and thus causes it to assume the form of an extra-uterine tumour, a process which is evidently Nature's attempt, often a successful one, to effect a cure. When this takes place and an intra-uterine polypus expelled from the uterus reaches the vagina the hæmorrhage it has given origin to is usually checked, or possibly may cease altogether. But in addition to these of intra-uterine origin, a polypus may grow from the cervical canal just within the os uteri or spring from the vaginal surface of the uterus.

Three varieties of polypus are recognised by pathologists—namely, the cystic or glandular, the mucous and the fibrous. The cystic or glandular polypus as the name indicates generally presents to the eye the appearance of cyst. These polypi are soft pearl-coloured bodies composed of an albuminous, gelatinous fluid, inclosed in a delicate membrane. They appear sometimes to be simply enlarged or hypertrophied or Nabothian glands, but are occasionally new growths. I pointed out to you an example of this latter form in one of the out-patients a few days ago, in whom a polypus grew from the lip of the os uteri, it was of the size and not very dissimilar in appearance to a grape, and had not caused hæmorrhage. When I attempted to seize it with the forceps it broke and discharged its contents. I cauterised its point of attachment freely with nitric acid, and when the woman presented herself again after the lapse of a few days no trace of this little polypus remained. In none of the cases of cystic polypus which have come under my observation have they been of greater size than a hazel nut or grape, nor am I aware of any instance in which they occurred high up in the uterus. They nearly invariably grow from some portion of the cervical canal. These polypi are always sessile, that is growing directly from their point of origin, without the intervention of a pedicle; two or more may and frequently do occur at the same time. When once detected they are easily destroyed either by pressure or by torsion. When situated within the cervical canal they generally give origin to a glairy discharge and nearly always cause hæmorrhage.

The mucous polypus may spring from any portion of the mucous surface of the uterus, but its favourite seat

seems to be the cervical canal, and it may not unfrequently be seen projecting from the mouth of the womb as a small tumour of a bright pink colour, which bleeds on the slightest touch.

These growths seldom attain a large size—once only have I met with an exception to this rule; the patient was the wife of a carman. I saw her about twenty-four hours after delivery and found a polypus of the size of an orange hanging partially out of the vagina. It was attached by a long and very slender pedicle to the cervix uteri, the point of attachment being just inside the os. The midwife who attended this woman assured me that her labour had been in all respects easy and natural, and she did not detect the polypus till after the expulsion of the placenta. Its vitality had evidently been destroyed by the pressure to which it had been subjected during the passage of the child's head through the vagina, for when I saw it it already exhibited signs of decomposition. This patient stated that having when in the third month of pregnancy lifted a heavy weight she felt something to give way internally, and perceived a tumour to appear at the vulva. Profuse hæmorrhage followed, which however shortly subsided and the tumour receded. During the remainder of pregnancy she enjoyed good health, and expecting that she felt when fatigued something to appear at the vulva, was not conscious of the existence of anything abnormal. A polypus of such a size as this springing from the cervical canal is however very rare.

The next largest I have seen occurred in one of our out-patients an unmarried woman aged twenty-four. Persistent hæmorrhage which all astringents failed to check compelled me to make a vaginal examination, and I discovered one of these mucous polypi nearly an inch and a quarter in length, but not much thicker than an ordinary quill, hanging out of the os uteri. In the great majority of instances however the mucous polypus does not attain a fourth of that size. These small ones are nearly entirely composed of a soft gelatinous structure. They are highly vascular and often give rise to severe hæmorrhage quite out of proportion to the size of the tumour. They are generally attached to the canal of the cervix by a slender pedicle and their vitality is very easily destroyed. It is not at all uncommon to meet with several small mucous polypi in the same patient; occasionally too they are of a denser texture, a greater proportion of fibro-cellular tissue entering into their structure, and when this is the case they are more likely to attain a large size. When once detected the removal of the mucous polypus is a matter of great ease. This can be effected either by means of a pair of curved scissors or by torsion. I greatly prefer the latter method; indeed I have seen such profuse hæmorrhage follow the excision of even a very small polypus that I do not think I shall ever again use a knife or pair of scissors for the purpose. I recommend you then always to remove them by seizing them firmly with a pair of fenestrated forceps and twisting them off, and then to cauterize their point of origin with nitric acid. When they project from the os uteri this is all that has to be done, but sometimes they lie higher up in the cervical canal and then you have to dilate the canal before you can reach them. Indeed this proceeding may of itself be sufficient to effect a cure, for so readily are these polypi destroyed by pressure, that instances are of not infrequent occurrence in which menorrhagia having led the physician to dilate the cervix that he may explore the uterus, he afterwards finds no morbid structure, the sea-tangle having by its pressure destroyed the polypus to which the menorrhagia was due. The fact of no polypus being found in any particular case is therefore not a proof that none existed.

Mucous polypi are occasionally met with springing from the fundus of the uterus, then their removal is a matter of more difficulty; for the cervix must be dilated throughout its whole extent, the polypus seized and twisted off, and nitric acid freely applied to the interior of the womb.

The fibrous polypus is even more frequently met with than

either of the other varieties and is more difficult to treat. The exciting cause and mode of growth of these tumours is still far from being clearly understood. We only know that as a rule they spring from the uterine sub-mucous tissue, are composed of firm fibro-cellular elements, and are invariably covered with mucous membrane. In fact they are "out-growths of and from the substance of the uterus, the mucous membrane and the muscular and fibrous tissue of the uterus growing in a variety of proportions into its cavity" (Paget). These polypi are generally supplied with numerous blood-vessels, which however are seldom of any magnitude. They are met with of all sizes, nor does the amount of hæmorrhage necessarily bear any proportion to the size of the tumour; they may be small and sessile, but more commonly are connected to the wall of the uterus by a well-defined pedicle, which however varies greatly in thickness and length. We seldom find more than one fibrous polypus in the uterus at the same time. I am aware however that there are exceptions to this rule; thus I had the opportunity recently afforded me by my friend Dr. Kidd of seeing a patient from whom he removed nine fibrous polypi at one operation.

The fibrous polypus generally grows from the fundus of the uterus, though examples from time to time occur of its being attached to other portions of uterine walls. I have never however in my own practice seen one springing from the cervical canal. But no matter where attached its course is the same—the polypus gradually enlarges while the whole of the uterus, stimulated apparently by its presence, increases in bulk and density, till not unfrequently we are enabled to feel the organ above the pubes. If not interfered with, and that it be pedunculated, it is possible that in time the uterus may expel it, and that thus it may become extra-uterine and even appear at the vulva. Such a course however is far from usual. In general the hæmorrhage which almost invariably accompanies this affection, runs down the patient, and compels her to seek for relief long before that stage can be reached, or, if she fail to obtain the requisite aid, consigns her to a premature grave.

The symptoms marking the occurrence of polypus are threefold—namely, hæmorrhage, leucorrhœa, or pain. Hæmorrhage is, I may say, invariably present. The patient generally first notices that the menstrual flow is more profuse than formerly, then that its duration is prolonged, and that leucorrhœa occurs in the interval; pain above the pubes and over the ovaries is also generally complained of. No age from puberty upwards possesses an immunity from this disease. Here on the table are specimens of four intra-uterine fibrous polypi removed from patients aged respectively, twenty-four, forty-six, thirty-five, and fifty-three years, the two former being from unmarried, the two latter from married women. The first specimen is the one you saw recently removed from M. D. who has just been discharged from this hospital. Her case is a very interesting and instructive one. She is aged but twenty-four years and is unmarried. Three years ago she began to notice the catamenia to be more profuse than natural; they have continued so ever since. About a year ago she for the first time began to experience pains in the left side of the abdomen, which at one point was tender to the touch; lying on that side too caused her much distress, but she was still able to hold a situation as housemaid. On the 8th of August last the catamenia came on suddenly and so very profusely as to cause faintness. On admission to hospital a day or two subsequently there was little or no discharge present, but the hæmorrhage had been of so alarming a character that I deemed it necessary though she was an unmarried woman to institute a vaginal examination. The vagina was moderately relaxed, the cervix appeared to be healthy, but the body was anteflexed and heavy. The sound penetrated to the depth of three inches. The cause of the hæmorrhage being still uncertain I proceeded in accordance with my invariable rule under such circumstances to dilate the cervix, and with some difficulty succeeded in introducing

several pieces of sea-tangle bougie. but on attempting to | mav break. and all the trouble has to be gone over again, from whom the how you was re-

then be with- re écraseur at d f we were using int of fact the useur.

Master of the an opportunity s écraseur of a grew from the who was very anemic, had been admitted on account of the hamior-

times almost despairs of being able to carry the wire round | anterior lip of the os uteri. The patient who was very the tumour, and even when this is accomplished your wire | anemic, had been admitted on account of the hamior-

seems to be the cervical canal, and it may not unfrequently be seen projecting from the mouth of the womb as a small tumour of a bright pink colour, which bleeds on the slightest touch.

These growths seem to have I met with in the wife of a carpenter a few hours after delivery an orange hanging part attached by a long and narrow pedicle to the uteri, the point of attachment being at the cervix. The midwife who attended her labour had been called in when she did not detect the existence of the placenta. Its removal was effected by the pressure to which it was subjected by the passage of the child's head. The patient stated that during her pregnancy lifted a heavy weight in her way internally, and in consequence of this the vulva. Profuse hæmorrhage followed shortly subsided and the patient during the remainder of pregnancy expecting that she felt well. The hæmorrhage from the vulva, was not considered abnormal. A polypus was removed from the cervical canal.

The next largest I have met with in patients an unmarried woman who had hæmorrhage which allayed my suspicions and compelled me to make a vaginal examination. I found one of these mucous polypi projecting from the os in length, but not much protruding from the os hanging out of the os. In some instances however the polypus is the fourth of that size. They are generally composed of a soft gelatinous substance vascular and often gelatinous. They are out of proportion to the size of the os generally attached to the cervix by a short pedicle and their vitality is generally not at all uncommon to the cervix. Polypi in the same patient are not infrequently of denser texture, a greater size, and entering into their structure. In such cases they are more likely to be detected and their removal is effected with great ease. This can be done by a pair of curved scissors (the latter method; indeed hæmorrhage follows the excision) or by the use of that I do not think I should recommend the use of scissors for the purpose. They may be removed by sequestered forceps and cauterized their point of attachment. If they project from the os they may be removed, but sometimes they are in the canal and then you have to dilate the cervix to reach them. Indeed I have seen them destroyed by pressure, the occurrence in which menorrhagia is due. The fact that the cervix dilates to dilate the cervix that afterwards finds no morbid condition. The fact that by its pressure destroyed menorrhagia was due. The fact that any particular case is the same as the last.

Mucous polypi are occasionally met with at the fundus of the uterus, and are more difficultly removed; for the removal of its whole extent, the use of nitric acid freely applied is necessary.

The fibrous polypus is even more difficultly removed than the mucous.

either of the other varieties and is more difficult to treat. The exciting cause and mode of growth of these tumours is still a matter of conjecture.

several pieces of sea-tangle bougie, but on attempting to withdraw them after the expiration of twenty-four hours I experienced great difficulty, for the os internum was so rigid that it had prevented the tangle expanding at that point in at all the same degree that it had in the cavity of the womb, and each piece when finally extracted was found to be constricted in the centre. A larger number were now introduced; next day on removing these I found the cervix to be freely dilated throughout its whole length, and on introducing the finger I detected a polypus of considerable size which was attached to the anterior wall of the uterus near the fundus by a short thick pedicle, the apparent antelexion of the uterus being due to the fact that the anterior wall was bulged outwards by the polypus as shown in Plate II. To effect this examination the anterior lip had to be seized by a vulsellum and the uterus drawn down in the manner described in my last lecture. The position, size, and shape of the polypus being thus ascertained the next step was to remove it. I shall detail to you exactly how this was effected in the case I am referring to. It will serve as a description of how the operation should be performed in all similar cases.

The uterus being drawn down as low as possible by means of the vulsellum which was fixed in the anterior lip, the index-finger of the right hand was again introduced till its tip touched the polypus. Another strong vulsellum such as that shown in Plate II. was then taken in the left hand and guided up to the polypus along this finger, and the tumour firmly grasped by it. The instrument being entrusted to an assistant the anterior lip was freed from the one by which it was held. This was done in order to give more room in the vagina, but unless the polypus be a firm one the hold we have obtained on the lip of the womb should not be let go.

Firm traction was now exerted on the polypus by means of the vulsellum with which it was grasped, and it was down as low as possible in the pelvis. A long *écraseur* made much on the pattern of that suggested by Dr. Braxton Hicks (Plate III.), and armed with a strong iron wire was then introduced, the wire being passed over the handles of the vulsellum so as to surround them. The extremity of the *écraseur* being kept in contact with the finger was guided up to the polypus, and the wire was after some difficult manipulation got over the upper surface of the polypus. The point of the *écraseur* was then pressed firmly against the lower edge of the pedicle and kept in as close contact as possible with its point of attachment to the uterine wall. This is a matter of great importance, for if the point of the instrument be kept in the position described the wire will be drawn as the *écraseur* is worked close to the base of the pedicle, and thus the whole of the tumour will be removed. The *écraseur* was then slowly but steadily worked, the pedicle cut through in a few minutes, and the polypus, still held by the vulsellum, extracted. The whole of the inner surface of the uterus was then brushed over with strong nitric acid, with the double view of preventing hæmorrhage and of destroying any unhealthy condition of the mucous membrane of the uterus, should such exist. The patient was of course under the influence of chloroform during the operation. The accompanying drawing (Plate III.) shows the position of a polypus at the fundus grasped by the vulsellum and with the *écraseur* applied. The point of the instrument should however be in closer contact with the uterine wall than it appears to be in the plate. This patient recovered without having the least drawback, was allowed to walk about the ward in a few days, and has since menstruated normally. This operation, though it is so easily detailed, is most difficult to perform, the polypus is quite out of sight, and can hardly be touched by the finger even when drawn down with the vulsellum; then the space so contracted is in which you must have at least two instruments, as well as your finger, that one sometimes almost despairs of being able to carry the wire round the tumour, and even when this is accomplished your wire

may break, and all the trouble has to be gone over again, as occurred in the case of the woman from whom the largest of the tumours which I now show you was removed.

In the case I have just detailed I used a strong iron wire, and though the base of the polypus was three-quarters of an inch in diameter it was sufficient for the purpose, still as already mentioned a single iron wire cannot be relied on if the pedicle be thick. I formerly used a cable of wire twisted tightly together, but some of the strands always gave way, and the ends becoming entangled in the parts or getting twisted round the extremity of the *écraseur* prevented it working, and I have been obliged to give them up. Dr. Kidd, in a recent operation at which I was present, cut through a very thick dense, pedicle with a strong steel wire such as those used for piano strings, and I think this suggestion will prove very useful. He also found that the steel wire was more easily manipulated in the uterus, for the loop which is always constricted in passing through the os expands from the effects of its own elasticity on reaching the cavity of the uterus.

The extreme difficulty of encircling an intra-uterine polypus with a wire or chain induced Dr. Marion Sims to invent an intra-uterine *écraseur* which is a marvel of ingenuity, but it is very complex, and in practice has proved a failure. I tried it in two cases, and found that it was impossible to adjust, and I have been compelled to abandon its use.

The same reason influenced me, and led me to consider whether a less complicated instrument could not be devised which would enable the operator to attain the desired end, and I have accordingly had this *écraseur* (Fig. 5) made by Weiss. It differs from an ordinary long wire *écraseur* only in having the end modified so as to allow of the passage through it of two slender silver tubes identical with those so well known as "Gooch's canulæ." These (a, a) armed with a wire (b, b) of any strength can be passed with ease up to the base of any polypus; they are then to be separated, and while one is held firmly the other is to be carried round the pedicle; this can always be accomplished when a silk or hempen ligature is used, but it is very difficult indeed to carry a stiff wire round a large tumour with them, but I have done it, and cases from time to time occur in which this method proves useful. Having once got the wire round the tumour the canulæ are to be passed through the openings (c, c) in the extremity of the *écraseur*; the *écraseur* is then to be pushed up, guided by the canulæ, till it comes in contact with the pedicle of the polypus; the canulæ can then be withdrawn, and the wire being attached to the *écraseur* at d and e, the operation is to be completed as if we were using an ordinary wire *écraseur*. This is in point of fact the adapting of the canulæ of Gooch to the *écraseur*.

Through the kindness of Dr. Johnston, Master of the Rotunda Lying-in Hospital, I had recently an opportunity of witnessing the removal by means of this *écraseur* of a very large fibro-cellular polypus, which grew from the anterior lip of the os uteri. The patient who was very anæmic, had been admitted on account of the hæmor-

rhage. The polypus was so large that it filled the whole vagina, and it was impossible to reach the pedicle or carry a wire round it with the fingers, the space being so very limited, Dr. Johnston therefore decided on encircling it by means of these canulæ; this was very skilfully accomplished by Dr. Denham, Dr. Johnston in consequence of an injury received in his hand being unable to operate himself; the wire, a strong iron one however broke after the *écraseur* had been worked for a few seconds; a rope of twisted wire was then tried, it too was carried round the tumour by the same means, but it also broke. A strong steel wire was then had recourse to; considerable difficulty was experienced in encircling the polypus with it on account of its stiffness, but at last with the aid of the canulæ this was effected, and the wire having been attached to the *écraseur* we had the satisfaction of finding it equal to the great strain to which it was subjected, and the pedicle was severed in a few moments. The tumour however was so large that it could not be extracted till both blades of an ordinary midwifery forceps had been applied. This case afforded a satisfactory proof both of the advantages which under certain circumstances are to be derived from this modification of the *écraseur*, and of the great superiority which the steel wire possesses over either the iron wire or twisted wire ropes.

There has no greater advance been made in uterine surgery than in the treatment of intra-uterine polypus; before the method of dilating the cervix uteri was introduced, it was impossible to diagnose their presence with any degree of accuracy. We might suspect their existence from the occurrence of hæmorrhage, and of uterine leucorrhœa but nothing more; now to use S. Marion Sims's language: "We can determine with the minutest accuracy not only their presence, but the size, shape, position, relations and attachments of all such tumours," and by means of the *écraseur* remove them in a short time without pain to the patient who is under the influence of chloroform, and without risk to her life.

But a fibrous polypus may spring from the vaginal portion of the cervix as well as from the interior of the uterus; its removal is then comparatively an easy matter, for unless the bulk be very great the chain or wire of an *écraseur* can be carried round it without much difficulty, and its separation is accomplished in a few minutes; these polypi as well as intra-uterine which having been expelled from the womb have become vaginal, do not bleed so freely as those contained within the uterus. Dr. McClintock, in his work "On Diseases of Women," relates a striking example of this, he removed an enormous fibrous polypus which weighed thirty-four ounces, from the vagina of a woman aged fifty, and yet for two years previously she had not had any red discharge.

In addition to the three classes of polypus of which I have just spoken, and which are undoubtedly out-growths from some portion of the uterine substance, two others are recognised by pathologists to which I must allude. The one is termed the fibrinous, and is looked upon by some authorities as the result of abortion. "The embryo having been extruded, the remains of the ovum left behind, forms with the extravasated blood the foundation of a fibrinous polypus;" others believe these tumours to be "metamorphosed and adherent coagula of retained menstrual blood." More recently the possibility of the remains of the placenta being capable of giving rise to polypoid bodies in the uterus has been advocated. Dr. Stadfeldt of Copenhagen maintains this view with much ability in a paper, a translation of which by Dr. W. D. Moore, will be found in the *Dublin Quarterly Journal* for November, 1863, from which I have quoted the foregoing extracts, and the perusal of which will amply repay any of you who desire to become better acquainted with this subject. Dr. Stadfeldt does not believe that those small portions of the after-birth, which nearly always remain after the placenta has been detached, and which usually come away with the lochia are capable even if retained, of giving origin to these

growths, but only when portions varying in size "from that of a walnut to that of a goose egg or larger, and which contain one or more colytedons of the placenta" are left behind, and remain firmly attached to the uterine wall; ably adduced however as are the arguments of Dr. Stadfeldt, I am not satisfied that his views are borne out by the facts brought forward in support of them—they amount to this: that in four cases large portions of the placenta were found after death adherent to the uterus in women recently delivered, the longest interval which elapsed between delivery and death being but four weeks; in his other cases but a few days intervened. With similar instances every obstetric physician is familiar.

In the case related at the conclusion of my last lecture, I removed a portion of placenta which had been retained in the womb for nearly ten weeks after delivery, and which doubtless was during that time gradually being loosened from its attachment to the uterine wall, and its connection probably only completely severed by the traction I made use of; that it was still connected with the uterus, we may I think safely infer from the fact that the mass was not in any degree decomposed, but the persistence of vitality in a portion of placenta adherent to the uterus is a very different thing from its development into a polypus.

## BRITISH ASSOCIATION

FOR THE

ADVANCEMENT OF SCIENCE.

---

FORTY-FIRST MEETING, HELD AT EDINBURGH.

---

AUGUST 3RD TO 8TH, 1871.

THE great scientific congress has again been held, and its proceedings once more make great demand on our space. They have, however, been very fully reported by the general press, and we now therefore only cull those portions of most interest to the Profession. We cannot, however, pass over the Presidential Address. Although unable to find room for it in full we give an abstract.

ON the 3rd the first general meeting of the Association was held at 8 p.m. Professor Huxley, in resigning his seat, thanked the Association for the honour conferred upon him, and its officers for their cordial and valuable assistance. He then paid a warm tribute to the great merits of his successor, to whom he gave up his chair. Sir William Thompson, the new president, then entered upon the duties of his office, and proceeded to deliver the customary inaugural address.

Sir WILLIAM THOMPSON referred in the first place, to the connection of the Association with Edinburgh through the honoured names of some of its founders, and quoted from a former address by Sir David Brewster, a brief account of the "small band of pilgrims who carried the seeds of the institution into the more genial soil of our sister land." "Sir John Robinson, Professor Johnston, and Professor J. D. Forbes were the earliest friends and promoters of the British Association. They went to York to assist in its establishment, and they found there the very men who were qualified to foster and organise it. Headed by Sir Roderick Murchison, one of the very earliest and most active advocates of the Association, there assembled at York about 200 of the friends of science." A letter written by Brewster in February, 1831, to Professor Phillips at York carries back the history to an earlier date, and contains inquiries as to the accommodation to be obtained in the city for a large meeting (probably of 100 persons!), and as to the willingness of the Mayor and other influential persons to promote the aims that were in view—namely, "to make the cultivators of science acquainted with each other, to stimulate them to new exertions, to bring the objects of science more before the public eye, and to take measures for

advancing its interests and accelerating its progress." Of the four pilgrims from Scotland to York not one now survives, and of the seven first Associates one more has gone over to the majority since the Association last week. Vernon Harcourt is no longer with us, but his influence remains. Brewster was the founder of the British Association; Vernon Harcourt was its lawyer. His code is to this day the law of the Association. On the 11th of May last Sir John Herschel died in the 80th year of his age, leaving a name that is a household word throughout the whole civilised world, and discoveries which, in the hands of Stokes, Sylvester, and Gregory, have served as foundations for progress alike in physics and in pure mathematics. Of his gigantic work in astronomical observation I need say nothing. Doubtless, a careful account of it will be given in the "Proceeding of the Royal Society of London," for the next anniversary meeting. In the past year also, another representative man of British science is gone, in the person of Professor De Morgan. His great book on the differential calculus was, for the mathematical student of 30 years ago, a highly-prized repository of all the best things that could be brought together under that title. It is no less valuable now; and if less valued, may not this be because it is too good for examination purposes, and because the modern student, labouring to win marks in the struggle for existence, must not suffer himself to be beguiled from the stern path of duty by any attractive beauties in the object of his study? One of the most valuable services to science which the British Association has rendered has been the establishment and maintenance of the Kew Observatory. Built originally for George III., and left for many years unused, it was granted by the Commissioners of Woods and Forests, in 1842, on the application of Sir Edward Sabine, for the purpose of carrying out and promoting observations upon the pendulum. Individual Fellows of the Royal Society and members of the British Association supplied the initial funds, and the work has been conducted by a committee of the Association, and assisted by grants from the funds. The institution now enters upon a new stage of existence, thanks to the noble liberality of a private benefactor. Mr. Gassiot's gift of £10,000 secures its future operation, without the necessity of further support from the Association. The success of the Kew Observatory, and the great value of the work done there, afford an example of the great gain to be earned for science by the foundation of physical observatories and laboratories for experimental research, to be conducted by qualified persons, whose duties should be, not teaching but experimenting, and such observatories and laboratories, here as upon the Continent, should be provided and fostered by the State. The physical laboratories which have grown up in the Universities of Glasgow and Edinburgh, and in Owen's College, Manchester, show the want felt of colleges of research; but they go but infinitesimally towards supplying it, being absolutely destitute of means, *matériel*, or *personnel* for advancing science, except at the expense of volunteers, or for securing that volunteers shall be found to continue even such little work as is at present carried on. Besides abstracts of papers read and discussions held before the sections the annual volumes of the Association contain much valuable matter in the shape of reports on particular branches of science from men well qualified to prepare them. Some of these have led to vast practical results; others, of a more abstract character, are valuable as powerful and instructive condensations and expositions of the branches of science to which they relate. I cannot better illustrate the two kinds of efficiency realised in this department than by referring to Cayley's "Report on Abstract Dynamics" and Sabine's "Report on Terrestrial Magnetism." I believe that it is due to the scientific character of the Admiralty "Compass Manual," based upon the joint work of Sabine and Archibald Smith, that no iron ship of Her Majesty's Navy has ever been lost by errors of the compass. The "Manual" is adopted as a guide by all the navies of the world. It has been translated into Russian, German, and Portuguese, and it is at present being translated into French. In the reports of the early years of the British Association we find also evidence of the diligent cultivation of the science of terrestrial magnetism, into which research is still being steadily pursued. Materials from scientific travellers of all nations, from our own magnetic observatories, from the magnetic observatories of St. Helena, the Cape, Van Diemen's Land, and Toronto, and from the scientific observatories of other countries have been brought together by Sabine. Silently, day after day, night after night, for a quarter of a century he has toiled, with one constant assistant always by his side, to reduce these

observations. At this moment, while we are here assembled, I believe that in their quiet summer retirement in Wales Sir Edward and Lady Sabine are at work on the magnetic chart of the world. If two years of life and health are granted to them, science will be provided with a key which must powerfully conduce to the ultimate opening up of one of the most refractory enigmas of cosmical physics, the cause of terrestrial magnetism. To give any sketch, however slight, of scientific investigation performed during the past year would, even if I were competent for the task, far exceed the limits within which I am confined; and I can only select some of those which have struck me as most notable. Great service has been done to science by the British Association in promoting accurate measurement in various subjects. To the non-scientific imagination this seems a less lofty and dignified work than looking for something new. But nearly all the grandest discoveries of science, including Newton's discovery of the law of gravitation, have been but the rewards of accurate measurement and patient long-continued labour in the minute sifting of numerical results. The origin of exact science in terrestrial magnetism is traceable to Gauss's invention of methods of finding the magnetic intensity in absolute measure. Weber extended the practice of absolute measurement to electric currents, the resistance of an electric conductor, and the electromotive force of a galvanic element. He made the beautiful discovery that resistance and the reciprocal of resistance are each of them a velocity. He made an elaborate and difficult series of experiments to measure the velocity which is equal to the conducting power, in electro-static measure, and at the same time to the resistance in electro-magnetic measure, in one and the same conductor. Maxwell discovered that this velocity is physically related to the velocity of light. The most accurate possible determination of Weber's critical velocity is just now a primary object of the Association's Committee on Electric Measurement, and it is at present premature to speculate as to the closeness of the agreement between that velocity and the velocity of light. This leads me to remark how much science, even in its most lofty speculations, gains in return for benefits conferred by its application to promote the social and material welfare of man. Those who perilled and lost their money in the original Atlantic telegraph were impelled and supported by a sense of the grandeur of their enterprise, and of the world-wide benefits which must flow from its success; they were, at the same time, not unmoved by the beauty of the scientific problem directly presented to them, but they little thought that it was to be immediately through their work that the scientific world was to be instructed in a long neglected and discredited fundamental electric discovery of Faraday's; or that, again, when the assistance of the British Association was invoked to supply their electricians with methods for absolute measurement (which they found necessary to secure the best economical return for their expenditure, and to obviate and detect those faults in their electric material which had led to disaster), they were laying the foundation for accurate electric measurement in every scientific laboratory in the world, and initiating a train of investigation which now sends up branches into the loftiest regions of and subtlest æther of natural philosophy. Long may the British Association continue a bond of union and a medium for the interchange of good offices between science and the world. The greatest achievement yet made in molecular theory of the properties of matter is the kinetic theory of gases, shadowed forth by Lucretius, definitely stated by Daniel Bernoulli, largely developed by Herapath, made a reality by Joule, and worked out to its present advanced state by Clausius and Maxwell, who have completed the dynamical explanation of all the known properties of gases, except their electric resistance and brittleness to electric force. The progress of spectroscopic research has led to important results with regard to the solar atmosphere and to the corona seen round the dark disc of the moon eclipsing the sun. It seems to have been proved that at least some sensible part of the light is a terrestrial atmospheric halo or dispersive reflection of the light of the glowing hydrogen and "helium" round the sun. I believe I may say on the present occasion, when preparation must again be made to utilise a total eclipse of the sun, that the British Association confidently trusts to our Government exercising the same wise liberality as heretofore in the interests of science. The results of spectrum analysis have also given finally conclusive proof against Mayer's hypothesis, that the sun's heat is supplied dynamically from year to year by the influx of meteors. Most important steps have recently been taken towards the discovery of the nature of

comets, establishing with nothing short of certainty the truth of a hypothesis which had long appeared to me probable, that they consist of meteoric stones; accounting satisfactorily for the light of the nucleus, and giving a simple and rational explanation of phenomena presented by the tails of comets, which had been regarded by the greatest astronomers as almost preternaturally marvellous. It is thoroughly proved, by the investigations of Professor Newton, of Yale College, followed and completed by those of Adams, that Temple's comet I., 1866, consists of an elliptic train of minute planets, of which a few thousands or millions fall to the earth annually about the 14th of November, when we cross their track. We have probably not yet passed through the very densest part; but thirteen times we have passed through a belt greatly denser than the average. The densest part of the train, when near enough to us, is visible as the head of the comet, and according to Tait's theory, is self-luminous by reason of collisions among its constituents; while the tail is merely a portion of the less dense part of the train, illuminated by sunlight, and visible or invisible to us according to circumstances not only of density, degree of illumination and nearness, but also of tactic arrangement, as of a flock of birds, or the edge of a cloud of tobacco smoke. The essence of science consists in inferring antecedent conditions and anticipating future evolutions from phenomena which have actually come under observation. In biology the difficulties of successfully acting up to this ideal are prodigious. The earnest naturalists of the present day are, however, not appalled by them, and are struggling to pass out of the mere "natural history stage" of their study and to bring zoology within the range of natural philosophy. An ancient speculation, still clung to by many, supposes that, under meteorological conditions different from the present, dead matter may have run together or crystallised or fermented into "germs of life," or organic cells, or "protoplasmia." But science brings a vast mass of inductive evidence against this hypothesis of spontaneous generation, as you have heard from my predecessor in the Presidential chair. Careful enough scrutiny has, in every case up to the present day, discovered life as antecedent to life. I am prepared to hear that "our code of biological law is an expression of our ignorance as well as of our knowledge." And I say, let any one who is not satisfied with the purely negative testimony of which we have now so much throw himself into the inquiry. Such investigations as those of Pasteur, Pouchet, and Bastian are among the most interesting and momentous in the whole range of natural history; and their results, whether positive or negative, must richly reward the most careful and laborious experimenting. I confess to being deeply impressed by the evidence put before us by Professor Huxley, and I am ready to adopt, as an article of scientific faith, true through all space and through all time, that life proceeds from life, and from nothing but life. How, then, did life originate upon the earth? Did grass and trees and flowers spring into existence, in all the fulness of ripe beauty, by a fiat of Creative power? or did vegetation, growing up from seed sown, spread and multiply over the whole surface? Every year thousands, probably millions, of fragments of solid matter fall upon the earth; and it is often assumed that all, and it is certain that some, meteoric stones are fragments which have been broken off from larger masses and launched free into space. It is as sure that collisions must occur between great masses moving through space as it is that ships, steered without intelligence directed to prevent collisions, could not cross and recross the Atlantic for thousands of years without them. Should the time when this earth comes into collision with another body, comparable in dimensions to itself, be when it is still clothed as at present with vegetation, many great and small fragments carrying seed and living plants and animals would undoubtedly be scattered through space. Hence, we must regard it as probable in the highest degree that there are countless seed-bearing meteoric stones moving about through space. If at the present moment no life existed upon this earth, one such stone falling upon it might, by what we blindly call natural causes, lead to its becoming covered with vegetation. The hypothesis that life originated on this earth through moss-grown fragments from the ruins of another world may seem wild and visionary; all I maintain is that it is not unscientific. From the earth stocked with such vegetation as it could receive meteorically to the earth teeming with the plants and animals which now inhabit it the step is prodigious, and I have always felt that the hypothesis of "the origin of species by natural selection" does not contain the true theory of

evolution, if evolution there has been, in biology. Sir John Herschel, in expressing a favourable judgment on the hypothesis of zoological evolution, with, however, some reservation in respect to the origin of man, objected to the doctrine of natural selection that it was too like the Lapsutan method of making books, and that it did not sufficiently take into account a continually guiding and controlling intelligence. This seems to me a most valuable and instructive criticism. I feel convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Reaction against the frivolities of teleology, such as are found, not rarely, in the notes of the learned commentators on "Paley's Natural Theology," has, I believe, had a temporary effect in turning attention from the solid and irrefragable argument so well put forward in that excellent old book. But overpoweringly strong proofs of intelligent and benevolent design lie all around us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back upon us with irresistible force, showing to us through nature the influence of a free will, and teaching us that all living beings depend on one ever-acting Creator and Ruler.

At the conclusion of the address a vote of thanks to the President was moved by the Lord Justice-General, seconded by Sir Alexander Grant, and carried by acclamation. The President briefly returned thanks, and the proceedings then terminated.

## SECTION B.—CHEMICAL SCIENCE.

### THE PRESIDENT'S ADDRESS.

Professor ANDREWS delivered his opening address. He said—Amidst the vicissitudes to which scientific theories are liable, it was scarcely to be expected that the discarded theory of Phlogiston should be resuscitated in our day, and connected with one of the most important generalisations of modern science. The phlogistic theory, elaborated nearly 200 years ago by Beecher and Stahl, was not, it now appears, wholly founded on error; on the contrary, it was an imperfect anticipation of the great principle of energy, which plays so important a part in physical and chemical changes. The disciple of phlogiston, ignorant of the whole history of chemical combination, connected, it is true, his phlogiston with one only of the combining bodies, instead of recognising that it is eliminated by the union of all. "There can be no doubt," says Dr. Crum Brown, who first suggested this view, "that potential energy is what the chemists of the 17th century meant when they spoke of phlogiston." "Phlogiston and latent heat," playfully remarks Cothard, "which formerly opposed each other in so hot a combat, have entered into a peaceful compact, and to banish all recollection of their former strife, have assumed in common the new name of energy." But, as Dr. Odling well remarks, "in interpreting the phlogistic writings by the light of modern doctrine, we are not to attribute to their authors the precise notion of energy which now prevails. It is only contended that the phlogistians had in their time possession of a real truth in nature, which, altogether lost sight of in the intermediate period, has since crystallised out in a definite form." But whatever may be the true value of the Stahlian views, there can be no doubt that the discoveries which have shed so bright a lustre round the name of Black mark an epoch in the history of science, and give a mighty impulse to human progress. A recent attempt to ignore the labours of Black and his great contemporaries, and to attribute the foundation of modern chemistry to Lavoisier alone, has already been amply refuted in an able inaugural address delivered a short time ago from the chair formerly occupied by Black. The statements of Dr. Crum Brown may indeed be confirmed on the authority of Lavoisier himself. Through the kindness of Dr. Black's representatives, I have been permitted to examine his correspondence, which have been carefully preserved, and I have been so fortunate as to find in it three original letters from Lavoisier to Dr. Black. Lavoisier addresses Black as one whom he was accustomed to regard as his master, and whose discoveries had produced important revolution in science. It may indeed be said with truth that Lavoisier completed the foundation on which the grand structure of modern chemistry has since arisen; but Black, Priestley Scheele, and Cavendish were before Lavoisier, and their claims to a share in the great work are not inferior to those of the illustrious French chemist. Proceeding to touch on questions of general chemistry at present attracting attention, the learned Professor spoke first of the relations

which subsist between the chemical composition and refractive power of bodies for light. He then referred to the "happy modification of the ice calorimeter," made by Bunsen. The principle of the method—to use as a measure of heat the change of volume which ice undergoes in melting—had already occurred to Herschel, and as it now appeared still earlier to Hermann; but their observations had been entirely overlooked by physicists, and had led to practical results. The ice calorimeter of Bunsen would therefore be welcomed as an important addition to their means of research. He then referred to the photo-chemical investigations now being prosecuted by Roscoe, which had been begun by him and Bunsen some years ago; and to Hunter's extension to the earlier experiments of Saussure on the absorptive power of charcoal for gases. The two new processes for improving the manufacture of chlorine, which attracted the attention of the section last year, were next referred to—one process being the discovery of Mr. Deacon, and the other that of Tessier de Mothay. A company had been lately formed in New York to apply Mothay's process to the production of a brilliant house-light. The conclusion of the address was devoted to some remarks on fermentation—the nature of which, and in particular of the alcoholic fermentation—had been lately discussed by Liebig with consummate ability.

## PAPERS.

Mr. JAMES DEWAR, F.R.S.E., then read a preliminary report on Thermal Equivalents of the Oxides of Chlorine.

Professor WILLIAMSON proposed a vote of thanks to Mr. Dewar for his report, as they were certainly greatly indebted to him for the results he had communicated to them. The vote was unanimously acknowledged.

The result of some experiments on Chemical Dynamics performed by Mr. J. H. Gladstone, F.R.S., and Mr. Alfred Tribe, F.C.S., were then communicated by Mr. Gladstone, illustrated by specimens, experiments, and illustrations.

Mr. CHARLES TOMLINSON, F.R.S., then read a paper "On the Behaviour of Supersaturated Solutions when exposed to the Open Air."

Mr. THOMAS AINSWORTH, of Cumberland, communicated a number of facts developed by the working of hæmatite ores in the Ulverstone and Whitehaven districts from 1844 to 1871. He referred first to some correspondence that had taken place between the British Association and the Government on the subject of the investigation of the hæmatite ore fields, and as this had resulted in the investigation being abandoned on the part of the Government Geological Survey, he thought it was the duty of every one who knew anything on the subject to make it public, seeing that when the Bessemer royalty expired—which would shortly be the case—this hæmatite would become much more valuable than it is at present. He quite agreed with all that had been done hitherto in this matter, and the facts he was now to present to them had come under his notice during the last thirty years while residing in Cumberland, near the Ulverstone and Whitehaven districts. Contrary to what had been generally supposed, he had found that hæmatite ore did not confine itself to the neighbourhood of limestone rock, but was to be found in many kinds of rock, and even between two different kinds of rock. He had also found that hæmatite had some relation to the coalfields, and was always found in close proximity to these. A peculiarity of the hæmatite ore fields was, that they seemed to run almost exactly from north-west to south-east. Another fact he had discovered was that carbonic acid was to be found only in very small quantities in hæmatite, while it was found in large quantities in ironstone.

## SECTION D.

This section includes zoology, botany, anatomy, physiology, and anthropology. The president of the Anatomical and Physiological branch, Professor Allen Thomson, delivered the opening address.

## PRESIDENT'S ADDRESS.

After an introduction as to arrangement of subjects treated by the section, he proceeded to say—The beneficial influence of the British Association in promoting biological research is made apparent by the number and importance of the reports on various subjects, as well as of the communications to the sections. Of the latter, the number received annually has been nearly doubled in the course of the last twenty years. Nor can it be doubted that this influence has been materially assisted by the contributions in money made by the Association in aid of various biological investigations; for it appears that, out of the whole sum of nearly £34,500 con-

tributed by the Association to the promotion of scientific research, about £2,800 has been devoted to biological purposes, to which it would be fair to add a part, at least, of the grants for palæontological researches, many of which must be acknowledged to stand in close relation to biology. The enormous extent of knowledge and research in the various departments of biology has become a serious impediment to its more complete study, and leads to the danger of confined views on the part of those whose attention, from necessity or taste, is too exclusively directed to the details of one department, or even, as often happens, to a subdivision of it. It would seem, indeed, as if our predecessors in the last generations possessed this superior advantage in the then existing narrower boundaries of knowledge, that they were able more easily to overtake the contemplation of a wider field, and to follow out researches in more than one of the sciences. To such combination of varied knowledge, united with their transcendent powers of sound generalisation and accurate observation, must be ascribed the widespread and enduring influence of the works of such men as Haller, Linnæus, and Cuvier, Von Baer, and Joannes Müller. There are doubtless brilliant instances in our own time of men endowed with similar powers; but the difficulty of bringing these powers into effectual operation in a wide range is now so great, that, while the amount of research in special biological subjects is enormous, it must be reserved for comparatively few to be the authors of great systems, or of enduring broad and general views which embrace the whole range of biological science. It is incumbent on all those, therefore, who are desirous of promoting the advance of biological knowledge to combat the confined views which are apt to be engendered by the too great restriction of study to one department. However much subdivision of labour may now be necessary in the origin, investigation, and elaboration of new facts in our science (and the necessity for such subdivision will necessarily increase as knowledge extends), there must be secured at first, by a wider study of the general principles and some of the details of collateral branches of knowledge, that power of justly comparing and correlating facts which will mature the judgment and exclude partial views. To refer only to one bright example, I may say that it can scarcely be doubted that it is the unequalled variety and extent of knowledge, combined with the faculty of bringing the most varied facts together in new combination, which has enabled Dr. Darwin (whatever may be thought otherwise of his system) to give the greatest impulse which has been felt in our own times to the progress of biological views and thought—(applause)—and it is most satisfactory to observe the effect which this influence is already producing on the scientific mind of this country, in opposing the tendency perceptible in recent times to the too restricted study of special departments of natural history. I need scarcely remind you that for the proper investigation and judgment of problems in physiology, a full knowledge of anatomy in general, and much of comparative anatomy, of histology and embryology, of organic chemistry and of physics, is indispensable as a preliminary to all successful physiological observation and experiment. The anatomist, again, who would profess to describe rationally and correctly the structure of the human body, must have acquired a knowledge of the principles of morphology derived from the study of comparative anatomy and development, and he must have mastered the intricacies of histological research. The comparative anatomist must be an accomplished embryologist in the whole range of the animal kingdom, or in any single division of it which he professes to cultivate. The zoologist and the botanist must equally found their descriptions and systematic distinctions on morphological, histological, and embryological data. And thus the whole of these departments of biological science are so interwoven and united that the scientific investigation of no one can now be regarded as altogether separate from that of the others. It has been the work of the last forty years to bring that intimate connection of the biological sciences more and more fully into prominent view, and to infuse its spirit into all scientific investigation. Having briefly referred to microscopic anatomical discovery, and touched at some length on the development theory, in regard to which he quoted from Professor Huxley's Presidential address of last year. The President continued—There is another topic to which I can refer with pleasure as connected with the cultivation of biological knowledge in this country, and that is the introduction of instruction in natural science into the system of education of our schools. (Applause.) It is so obvious, that whatever knowledge, easily acquired, and even though of the most elementary

kind, tends to enlarge the range of observation and thought, must have some effect in removing its recipients from grosser influences, and may even give information which may prove useful in social economy and in the occupations of labour. (Applause.) Nor need I point out how much more extended the advantages of such instruction may prove if introduced into the system of our secondary schools, and more freely combined than heretofore with the too exclusively literary and philosophical study which has so long prevailed in the approved British education. It is obvious, too, that while this more immediately useful or beneficial effect on the common mind may be produced by the diffusion of natural knowledge among the people, biological science will share in the gain accruing to all branches of natural science, by the greater favour which will be accorded to its cultivators, and the increased freedom from prejudice with which their statements are received and considered by learned as well as by unscientific persons. (Applause.) I cannot conclude these observations without adverting to one aspect in which it might be thought that biological science has taken a retrograde rather than an advanced position. In this, I do not mean to refer to the special cultivators of biology in its true sense, but to the fact that there appears to have taken place of late a considerable increase in the number of persons who believe, or who imagine that they believe, in the class of phenomena which are now called spiritual—(laughter and applause)—but which have been long known—since the exhibitions of Mesmer, and, indeed, long before his time—under the most varied forms, as liable to occur in persons of an imaginative turn of mind and peculiar nervous susceptibility. (Renewed laughter and applause.) It is still more to be deplored that many persons devote a large share of their time to the practice—for it does not deserve the name of study or investigation—of the alleged phenomena, and that a few men of acknowledged reputation in some departments of science have lent their names and surrendered their judgment to the countenance and attempted authentication of the foolish dreams of the practitioners of spiritualism, and similar chimerical hypotheses. (Laughter and applause.) The natural tendency to a belief in the marvellous is sufficient to explain the ready acceptance of such views by the ignorant; and it is not improbable that a higher species of similar credulity may frequently act with persons of greater cultivation, if their scientific information has been of a partial kind. It must be admitted, further, that extremely curious and rare, and to those who are not acquainted with nervous phenomena, apparently marvellous phenomena present themselves in peculiar states of the nervous system—some of which states may be induced through the mind and may be more and more liable to recur, and greatly exaggerated by frequent repetition. But making the fullest allowance for all these conditions, it is still surprising that persons otherwise appearing to be within the bounds of sanity—(laughter)—should entertain a confirmed belief in the possibility of phenomena which, while they are at variance with the best established physical laws, have never been brought under proof by the evidence of the senses, and are opposed to the dictates of sound judgment. It is so far satisfactory in the interests of true biological science that no man of note can be named from the long list of thoroughly well-informed anatomists and physiologists who has not treated the belief in the separate existence of powers of animal magnetism and spiritualism as wild speculations, devoid of all foundation in the carefully tested observation of facts. It has been the habit of the votaries of the systems to which I have referred to assert that scientific men have neglected or declined to investigate the phenomena with attention and candour; but nothing can be farther from the truth than this statement. Not to mention the admirable reports of the early French academicians, giving the account of the negative result of an examination of the earlier mesmeric phenomena by men in every way qualified to pronounce judgment on their nature, I am aware that from time to time men of eminence, and fully competent, by their knowledge of biological phenomena, and their skill and accuracy in conducting scientific investigation, have made the most patient and careful examination of the evidence placed before them by the professed believers and practitioners of so-called magnetic, phrenomagnetic, electro-biological, and spiritualistic phenomena; and the result has been uniformly the same in all cases when they were permitted to secure conditions by which the reality of the phenomena, or the justice of their interpretation, could be tested—viz., either that the experiments signally failed to educe the results professed, or that the experimenters were detected in the most shameless and determined impostures.

(Laughter and applause.) I have myself been fully convinced of this by repeated examinations. But were any guarantee required for the care, soundness, and efficiency of the judgment of men of science on these phenomena and views, I have only to mention, in the first place, the revered name of Faraday, and, in the next, that of my life-long friend, Dr. Sharpey, whose ability and candour none will dispute—(Applause)—and who, I am happy to think, is here among us, ready, from his past experience of such exhibitions, to bear his weighty testimony against all cases of *levitation*, or the like, which may be the last wonder of the day among the mesmeric or spiritual pseudo-physiologists. (Laughter and applause.) The phenomena to which I have at present referred, be they false or real, are in great part dependent upon a natural principle of the human mind, placed, as it would appear, in dangerous alliance with certain tendencies of the nervous system. They ought not to be worked upon without the greatest caution, and they can only be fully understood by the accomplished physiologist who is also conversant with psychology. The experience of the last hundred years tends to show that there will always exist a certain number of minds prone to adopt a belief in the marvellous and striking in preference to that which is easily understood and patent to the senses; but it may be confidentially expected that the diffusion of a fuller and more accurate knowledge of vital phenomena among the non-scientific classes of the community may lead to a juster appreciation of the phenomena in question, and a reduction of the number among them who are believers in the impossible. As for men of science who persist in submitting to such strange perversion of judgment, we can only hope that the example of their less instructed fellow-countrymen may lead them to allow themselves to be guided more directly by the principles of common sense than by the erratic tendencies of a too fervid imagination. (Loud and prolonged applause.)

**Medical Witnesses.**—In answer to Mr. C. Bentinck, on Thursday, Mr. Bruce said he had no personal knowledge of the allowance made to Mr. Oliver Pemberton, surgeon, of Birmingham, for attending the Carlisle Assizes as a witness on the Murphy riots,—second-class fare and a guinea; or of the opinion expressed by the Lord Chief Baron that the allowance ought to be largely increased; and no communication on the subject had been received by the Treasury, which had power to increase allowances under special circumstances.

**Inventions—New Vaccination Sleeve.**—We have much pleasure in stating that several improvements have been made in the vaccination sleeve lately described and illustrated in our columns, by Mr. R. Hanslip Sers, of Nottingham. These modifications render it thoroughly efficient for the purpose for which it is designed. The sleeve is made by Mr. Miller, of Leicester square, London, and will confer a boon on many a tender infant. Mothers will gladly pay half a crown to protect their children's arms from the friction of the clothes during the process of vaccination.

DR. D. W. THOMAS, of Leavenworth, Ks., reports the case of a farm labourer who, while standing astride of a revolving horizontal shaft, engaged in oiling a threshing machine while in rapid motion, allowed his pantaloons to become entangled on the shaft, and were wound on till the scrotum became enclosed, and wound round until it was torn from the body; stripping with it all the covering skin and fascia of the penis, the testes, the spermatic cords, and a portion of the perineum, leaving all of those organs exposed and unprotected. The cords were drawn out so as to be elongated two or three inches. The tissues, which had covered the penis were abruptly broken off at the glans, while the muscular surface of the perineum, including a portion of the inner surface of the thighs, was made bare. The skin and fascia were stripped off from the femoral artery, so that its pulsations were plainly visible. The wound of the thigh was dressed with deep sutures, and exposed testicles were covered with pledgets of lint, wet in a solution of sulphate of soda, covered with loose dressings. The formation of granulations was rapid and uninterrupted, and the result satisfactory. A well defined sac covers each testicle. A second case, nearly similar, was treated by the doctor in the same way, with not quite as good results, yet very satisfactory, considering the extensive injury.—*Leavenworth Medical Herald.*

### THE GOVERNMENT AND THE PROFESSION.

ONE more baronetcy has been conferred on a medical man. Mr. Paget has at last been gazetted to this honour, and the Profession will rejoice that so worthy a surgeon has no longer been passed over. To honour our leaders is to honour all. It would be superfluous to say one word in commendation of James Paget. What we do say—and have often said before—is, that more medical men should receive recognition from the State. Perhaps, now a leading surgeon has been recognised, a leading physician may also receive his reward. Dr. Burrows, the President of the College of Physicians, may be named, as he has long been known as a medical politician, and this class of men ought no longer to be passed over. But the fact is that a dozen or a score baronetcies bestowed upon leading medical men would not suffice to equalise our Profession with that of others. The neglect of medical men is a standing disgrace to the Government. On this account we are glad to see that our new monthly review—*The Doctor*—has taken up this subject with much spirit, and, in its last number, has denounced in strong terms the conduct of the Government in reference to the two medical men who were sent to represent England with the French Army in the late war. As we urged that English Military Surgeons should be sent, and congratulated the Government on its wise selection of Deputy Inspector-General Dr. Gordon, C.B., and Surgeon Major Wyatt, we may admit that we hear with amazement that neither of these men have been promoted, although they both endured the horrors of the siege of Paris. Why is this? We fear, with our contemporary, it is because they were *medical* officers only.

Now, the public ought to be informed of this, and, at the same time, told that *combatant* officers and others who, when danger approached, found excuses for absence, have been promoted, or otherwise rewarded. It is one of the greatest pieces of injustice that ever stained our annals.

The French Government itself has put our own to shame for its neglect of its own servants by making them officers of the Legion of Honour.

What ought to be done? We answer, these men ought to be promoted. The Deputy Inspector should be gazetted Inspector; the Surgeon Major should obtain a similar reward. We are told that promotion in the Guards cannot be given. Then let Wyatt have at least a C.B.; and, if the country is in so beggarly a condition that it cannot afford Gordon the pay of Inspector, give him brevet rank, or offer him to go on half pay as full Inspector, and give him the next step in his order, converting his C.B. into a K.C.B.

This would be far more worthy of England than to offer them permission to wear a foreign order, which we see Mr. Eastwick proposes in a motion to the House of Commons. For this reason we sincerely hope the Government will look at the justice of this case, as well as of the general fact—that the Medical Profession is, in this country, less recognised than in any other civilised community. Not merely public officials and public servants, but the Profession as a whole must be recognised, and that soon.

---

### CHOLERA.

THE approach of cholera gives a new interest to the returns of the Registrar-General, and makes Orders in Council and other sanitary matters subjects of general conversation.

We, last week, gave full particulars in respect to the advance of the dreadful pestilence, and now propose to continue the subject. After the issue of our last Number, a Medical inspector was sent to Hull to advise with the authorities.

It seems that on board three of the steamers from Cronstadt to Hull there have been fatal cases of cholera, but the health of Hull was never better than at the present moment, the death-rate for the fortnight ending on Wednesday being only 18.9 per 1,000 of the population. The Sanitary Committee of the Local Board of Health have taken the most prompt action with a view to prevent any importation of the dreadful malady. The chairman of that committee, Mr. Alderman Mayfield, first heard the cholera had occurred on board a Hull steamer, the *Burgos*, on Friday last. He at once conferred with the Mayor and the Board's law clerk, and the same day, before the arrival of the new Order in Council relating to cholera, he appointed temporarily a Medical Officer to board every ship arriving from Cronstadt, and put the Sanitary Inspector in motion, ordering the preparation of the Cholera Hospital—a wooden building, erected when the town was threatened with cholera in 1866.

At a meeting of the Sanitary Committee, held on Wednesday, the chairman's action was approved, and the following, among other resolutions, carried:—“That the Local Board, as the nuisance authority, hereby directs that the master of every ship arriving within the district from a place infected with the cholera having on board any person affected with the cholera, or the body of any person dead with the cholera, must anchor at a place in the Hull roads, at a distance of not less than 150 yards eastward of the Humber training ship, *Southampton*, in order that all persons on board such ship may be examined and certified, as required by the order.” The

Committee next appointed a Medical practitioner, Mr. J. F. Holden, to visit each ship arriving from an infected port. A resolution was also passed to circulate among shipmasters copies of the Order of Council. It was also resolved that the law clerk write to the Admiralty, asking for the loan of an old war vessel, to be fitted up and used as a hospital ship in the Humber. It was also resolved that the surveyor be empowered to take all necessary steps to place the public and private sewers and ditches within the Board's district in a thoroughly sanitary condition. Other resolutions of a like nature were also adopted.

Nor was this too soon, for Dr. Zuelzer, in forwarding to our Register-General his weekly return for Berlin, states that the reports as to Asiatic cholera are incomplete, but that it is certainly entering Riga on the Baltic, at the mouth of the Dwina. In Tambow, out of 30,000 inhabitants, 453 died from cholera in the week ending the 13th of July; this is in Central Russia, where the sanitary conditions are unfavourable.

There are many other incidents to be observed, but for the moment it may be well to set in array other facts from the same source.

We learn, then, with respect to the general health of the country, that the annual rates of mortality in the seventeen English towns, in the order of their topographical arrangement, were as follows:—London 23 (per 1,000); Portsmouth 11, Norwich 12, Bristol 22, Wolverhampton 13, Birmingham 20, Leicester 27, Nottingham 30, Livervool 27, Manchester 29, Salford 36, Bradford 15, Leeds 21, Sheffield 21, Hull 22, Sunderland 37, and Newcastle-upon-Tyne 37. The fatal cases of small-pox in these seventeen towns, which in the two previous weeks had been 264 and 268, declined to 222 last week; in Newcastle the deaths from this disease corresponded with the number in the previous week, while they showed a decline in each of the other towns. The fatality from diarrhoea, principally infantile, in these seventeen towns, which in the two previous weeks had been 129 and 195, rose last week to 340. The annual death-rate from diarrhoea in the week ending last Saturday was equal to 3 per 1,000 in London, 5 in Manchester and Salford, 2 in Liverpool, and 5 in Leeds.

In Edinburgh the annual rate of mortality from all causes last week was 25 per 1,000 persons living; in Glasgow, 33 per 1,000; and Dublin, 20.

From this we turn to the Metropolis, and here again are indications that ought not to be overlooked, as the following extract from the mortality returns will show:—

In London 2,137 births and 1,420 deaths were registered last week. After making due allowance for increase of population, the births were 33, and the deaths 339, below the average number in the corresponding week of the last ten years.

The mortality of the western group of districts was at the annual rate of 18, in the northern group of 24, in the central group of 23, in the eastern group of 26, and in the southern group of 22 per 1,000 persons living.

Zymotic diseases caused 468 deaths last week, including 122 from small-pox, 18 from measles, 19 from scarlet-fever, 8 from diphtheria, 22 from whooping-cough, 25 from different forms of fever (of which 9 were certified as typhus, 9 as enteric or typhoid, and 7 as simple continued fever), and 201 from diarrhoea; thus to the seven principal diseases of this class 415 deaths were referred last week, against 314 and 339 in the two preceding weeks.

The fatal cases of diarrhoea, which in three previous weeks had been 39, 64, and 110, further rose last week to 201. In addition to these, 17 deaths were referred to cholera and choleraic diarrhoea (against 4 and 9 in the two previous weeks) of which 13 were of infants not exceeding one year of age, and four were of adults aged between forty and sixty years. Two of the latter cases call for special notice on account of the short duration of the disease; a printer, aged fifty-six years, died on the 26th ult., in Richard street, Islington, of "choleraic diarrhoea, 25 hours' exhaustion;" and the wife of a crate maker, aged forty-four years, died on the same day at Armagh road, Bow, whose death was certified as "choleraic diarrhoea, 18 hours." It is highly important at the present time that the greatest energy should be used in securing prompt and efficient treatment in the earliest stages of diarrhoea, for it cannot be too generally known that all cases of cholera commence with diarrhoea.

The deaths from small-pox in London, which in the two previous weeks had been 133 and 135, declined last week to 122. In six permanent and temporary hospitals for this disease 54 deaths were recorded last week, of which 25, 10, and 14 respectively occurred in the institutions at Hampstead, Homerton and Stockwell. After distributing these deaths, it appears that 14 belonged to the west group of districts, 33 to the north, 8 to the central, 27 to the east, and 40 to the south; these numbers showed a slight increase in the east and south of London, while they had declined in each of the other groups of districts. Six deaths from small-pox were returned last week in Kentish town, and 4 each in Mile-end Old town, Eastern, St. Peter, Walworth, and Battersea sub-districts.

## Notes on Current Topics.

### Cholera Precautions at Liverpool.

THE threatened visitation of cholera was mentioned at the meetings of the Health Committee of the Town Council. Dr. Trench said although they did not expect that the cholera would come by that route, inasmuch as it had always come in the track of emigration from Hull, yet it seemed necessary that they should be prepared to meet any contingency that might arise. He suggested that the Committee might engage a piece of land for the erection of a hospital shed, in the event of a vessel arriving in the Mersey with cholera on board, and Dr. Radcliffe had favoured him with the form of a shed which had met the approval of the Medical Council. The requirement of the Privy Council was simply a small shed suitable for the reception of a certain number of males and females, and Dr. Radcliffe stated that the expense, with ample cubical space provided, was only £5 per bed. If, unfortunately, cholera came, it would be his duty at once to communicate the fact to the Mayor, and ask him, as in 1866, to call upon the Privy Council to put in force the Diseases Prevention Act, which would immediately transfer the care of all cases of cholera to the parochial authorities. At present, cases which came into the borough otherwise than by sea, would be taken charge of by the parochial authorities, the Order in Council applying only to those arriving by sea. To meet the real danger—that of the introduction of disease by emigrants—they should be very stringent with regard to the inspection of lodging-houses which received emigrants. It was resolved, "That the Staff Sub-committee be authorised to make a provisional contract for the erection of a temporary cholera hospital, if required, to contain not exceeding twenty beds, and to make such other arrangements as may be necessary."

### Progress of the Cholera.

On the 2nd of August the cholera epidemic crossed the Prussian frontier. The first case has occurred at Königsberg, where a Polish Jew was attacked by it and died. On the same day two other persons were reported ill, one of whom died. No further reports have arrived yet. The reports from Russia are unsatisfactory. On the 25th of July, 595 cholera patients were in the hospitals at Moscow, and the same day 102 fresh cases were reported. Up to that date there had been 3,125 cases, of which 1,428 proved fatal, in addition to those cases which may not have been reported to the authorities. At the same period there were 103 patients in Riga, and 55 new cases, with 48 deaths on the same day.

### New Sick Asylum for East London.

Last week the sick asylum, erected under the provisions of the Metropolitan Poor Act, for the accommodation of the sick of the parishes of Poplar, Bromley, Bow, Limehouse, Wapping, Shadwell, and Ratcliff, was opened for the reception of patients. The building consists of eight separate blocks, all of which are connected by a corridor 10 ft. wide, and upwards of 600 ft. long. The building is certified by the Poor-law Board to contain 572 beds, and the cubic space allotted to each patient varies from 1,000 to 1,500 ft. The whole asylum is warmed by hot-water coils. The building cost £43,000; this amount is defrayed from a loan made by the District Asylum managers.

### The Agitation in Favour of the Contagious Diseases Acts.

THE Sub-Committee for the Association for extending these Acts resolved, at a recent meeting, to postpone the general meeting of the members, which was to have been held when the report of the Royal Commission appeared, until the publication of the minutes of evidence, of which the Sub-committee hopes to lay before the Association and the public an impartial summary before Parliament reassembles next Session. In the meantime, the Association considers that it has much cause for congratulation in the result of the inquiry. The modification and extension of the Acts for the purpose of lessening disease, restraining immorality, and for obtaining legal power to remove young girls from a life of sin, which have throughout been the avowed objects of this Association, are, in the main, adopted by the Commission in their Report. This document has been drawn up after an exhaustive enquiry, in which every one who believed he or she had information to give, was allowed full liberty of speech and a patient hearing. It is most satisfactory to find that not one of the outrages so vividly described by certain opponents of the Acts has been proved to have actually occurred; and that, while disease among the troops quartered outside the districts of the Acts has increased and not diminished, it has fallen to less than one-half of its old prevalence where the Acts are put in force.

### Health of Dublin.

In the Dublin Registration District the births during the week amounted to 171. The average number in the corresponding week of the years 1864 to 1870 inclusive, was 156. The deaths registered during the week were 121.

The average number in the corresponding week of the previous seven years was 129. Ten deaths were caused by fever, viz., five by typhus and five by typhoid or enteric fever. Eight deaths from scarlet fever were registered. Diarrhœa caused four deaths, and dysentery one. Six deaths resulted from bronchitis, and three from pneumonia or inflammation of the lungs. Ten children died from convulsions. Two deaths were attributed to apoplexy, and one to paralysis. Phthisis, or pulmonary consumption proved fatal in eighteen instances, mesenteric disease in three, and hydrocephalus, or water on the brain, in one. Two deaths were ascribed to heart disease. One death was referred to inflammation of the kidneys, one to stone, and one to kidney disease unspecified. Four accidental deaths, and one case of homicide, were registered.

### Concentrated Lime Juice Syrup.

As a summer drink this, diluted with water, is most agreeable, apart from its valuable anti-scorbutic qualities. We have been trying a specimen of the syrup made by Mr. Lamplough, and can report favourably of it. It keeps very nice in hot weather and seems to be all that need be desired.

### College of Physicians.

WHY has not the last list of Fellows provoked the remonstrance of our contemporaries? Have they received a sop by the promotion of paragraphists? No wonder at the black-balling reported. It is a pity the Fellows did not black-ball the whole list. We confess to great surprise at the election. It is too bad to promote men who have done nothing, while others, many years senior, are left out in the cold. But, perhaps, they neither wrote paragraphs of news, nor had fathers nor uncles in office, nor knew how to earwig. The majority promoted certainly have waited too long. But how long have some other unfortunate members been passed over! Nothing but a radical reform will satisfy the Profession.

### Dr. Dorrington's Sauce.

THOSE who have been accustomed to the Sandringham Hot Sauce will be glad to learn that it is still to be bought under the above designation—the author having, for some reason, chosen to reveal his name. It is thoroughly wholesome and peculiarly piquant. Those who have not tried it, and find it difficult to obtain a condiment that suits both palate and stomach, should try Dr. Dorrington's.

### Order in Council on Cholera.

A NEW order has just been issued; after pointing out the powers conferred upon the Privy Council to make special provision against the introduction of epidemic disease, it says that it is requisite to take precautions as far as practicable, against the introduction of cholera into this country, and that the Lords of her Majesty's Most Honourable Privy Council, by virtue of the powers in this behalf in them vested, order as follows:—

1. In this order the term "ship" includes vessel or boat. The term "master" includes the officer or person for the time being in charge or command of a ship. The term "cholera" includes choleraic diarrhœa. The term

"nuisance authority" has the same meaning as in the Sanitary Act, 1866.

2. It shall be lawful for any nuisance authority having reason to believe that any ship arriving in its district comes from a place infected with cholera, to visit and examine such ship before it enters any port, or lands any person or thing in the district, for the purpose of ascertaining whether such ship comes within the operation of this order.

3. The master of every ship within the district of a nuisance authority, having on board any person affected with cholera, or the body of any person dead of cholera, or anything infected with or that has been exposed to the infection of cholera, shall, as long as the ship is within such district, moor, anchor, or place her in such position as from time to time the nuisance authority directs.

4. No person shall land from any such ship until the examination hereinafter mentioned has been made.

5. The nuisance authority shall, immediately on the arrival of such a ship, cause all persons on board of the same to be examined by a legally qualified medical practitioner, and shall permit all persons who shall not be certified by him to be suffering from cholera to land immediately.

6. All persons certified by the examiner to be suffering from cholera shall be dealt with under any rules that may have been made by the nuisance authority under the 29th section of the Sanitary Act, 1866; or where no such rules shall have been made, shall be removed, if their condition admits of it, to some hospital or place to be designated for such purpose by the nuisance authority; and no person so removed shall quit such hospital or place until some physician or surgeon shall have certified that such person is free from the said disease.

7. In the event of any death from cholera taking place on board of such vessel, the body shall be taken out to sea, and committed to the deep, properly loaded, to prevent its rising.

8. The clothing and bedding of all persons who shall have died, or had an attack of cholera, on board such vessel, shall be disinfected, or (if necessary) destroyed, under the direction of the nuisance authority.

9. The ship, and any articles therein which may be infected with cholera, shall be disinfected by the nuisance authority.

10. Every person obstructing the nuisance authority in carrying this order into effect, or otherwise offending against this order, shall be liable, on summary conviction, to a penalty not exceeding £20.

The difficulty of carrying out the precautions enjoined, is manifest in a statement made by the *Standard*, to the effect that, "notwithstanding the recent Order in Council as to precautions to be taken by nuisance authorities to overhaul ships arriving with cholera, and ships in which some one has died from cholera, two cases happened on Saturday, in which the clothes of men who died from cholera on board ship were landed and carried through our crowded streets. The nuisance authorities had actually allowed the ships to come in without stopping or detaining them, and then let the clothes of the deceased be carried about London. We have no means of knowing whether these clothes have been even yet destroyed. It is not easy to understand the value of Orders in Council and regulations if the nuisance and Customs authorities are the first to disregard them."

LAST week, in the metropolis, 1,420 deaths were registered; being 339 below the average. Zymotic or preventible disease caused 468 deaths, of which 122 were from small-pox, which is now steadily though slowly declining. Cholera and choleraic diarrhoea are credited with 17 deaths, and diarrhoea with 201.

### River Poisoning.

At a meeting held at Chester last week, some startling statements were made as to the impurity of the river Alyn, one of the streams flowing into the Dee. Tar, petroleum, and other noxious ingredients from various oil manufactories on the small streams are frequently seen floating upon the Alyn, and clinging in large masses nearly an inch thick to the bushes which overhang it. The farmers in the neighbourhood are unable to use the stream for the purpose of watering their cattle, and, at a distance of seventeen miles from the point at which the impurity found its way into the water, the stench after rain was almost unbearable, the horses would not drink of the water. The stench was not so perceptible lower down, where the water was more quiet, but as the Alyn entered the Dee, a short distance from the place whence the water supply of Chester was derived, there could be no doubt whatever of its injurious effect upon the citizens.

### Accidental Poisoning.

At an inquest held on Saturday last, where a lady had gone to her cupboard in the dark, and accidentally took up and drank from a bottle, containing corrosive sublimate, which resulted in death, Dr. Lankester, the coroner, took occasion to remark that, if some distinctive bottle, which, both to the touch as well as to the sight, disclosed the nature of its contents, were in general use, such accidents as these could not happen. He further stated that, unless the Medical Profession take some steps for the protection of life from poisoning at once, the Government would, very properly, interfere and compel them to do so.

### Physical Results of Trade Frauds.

THE effects of a well known species of trade fraud upon the health of those employed in it has been unequivocally exposed by the medium of a memorial sent to the Medical Department of the Privy Council:—

It is stated by the weavers of Todmorden, that for several years a material called China clay, has been introduced into the manufacture of calicoes and other grey goods. In some mills, sizing, including China clay, is laid on the warps to the extent of 40, 60, and even 100 per cent.; that before the American war the percentage was 20, and ingredients, believed to be poisonous are used to make the China clay adhere to the warps. To prevent the warps breaking, through the dryness of the atmosphere, it is necessary to close the ventilators in the weaving sheds, and, through the closing of the ventilators, the weavers are compelled to inhale the dust of the China clay that rises from the warps, mixed with the poisonous ingredients. Working in these sheds, they suffer from excessive heat and thirst, and are greatly distressed, especially in summer, when they are frequently compelled to leave their work to breathe the fresh air outside. The inhalation of this dust causes difficulty of respiration, loss of appetite, bronchitis, and consumption; and although the strong may bear up for a time against the injurious effects of the sizing, it tells upon them, apparently creating—certainly accelerating—lung disease, many are compelled to give up weaving, being forbidden by Medical men to return to the weaving sheds while China clay is used, that others work for a few weeks, and

are then compelled to abstain for days or weeks. That the beginning of fatal illness may apparently be traced to the working in weaving sheds wherein China clay is used.

The object of this process is to thicken the cloths, so as to make flimsy stuffs appear close and strong. This clay is known to the sempstress as "dressing."

### Irish Vital Statistics.—Quarterly Summary of the Health of Dublin.

*Births.*—In the Dublin district the number of births registered during the last quarter amounted to 2,189; being 1 in 35, or 28 in every 1,000 of the population. The number of births north of the river Liffey was 866, or 1 in 31; and on the south side of the river, 948, or 1 in 36 of the population. In the suburbs, the number of births registered amounted to 375, or only 1 in 43 of the population. There were registered in London during the same period an annual ratio of 1 in 30; in Glasgow, 1 in 24, and in Edinburgh 1 in 27.

*Deaths.*—The number of deaths in the Dublin district during the quarter amounted to 1,880, an annual ratio of 1 in 41, or 24 in every 1,000 of the population. The number north of the Liffey was 705, or 1 in 38 of the population; and the number south of the river was 880, 1 in 39 of the population. In the suburbs the number of deaths was 295—1 in 55. The number of deaths in London was 18,815—1 in 43, or 23 in every 1,000 of the inhabitants; in Glasgow, 1 in 28, and in Edinburgh, 1 in 37.

*Diseases.*—Fever proved fatal in 108 instances, being an increase of 16 as compared with last year. Of the deaths from fever 32 were returned as typhus, 50 as typhoid or enteric, and 26 as simple continued fever. Of the total deaths registered 1 in every 17.4 was caused by fever. Fifty deaths were caused by scarlet fever; in the corresponding quarter of last year 80 persons died from this disease. The deaths from small-pox amounted to 9. Croup caused 30 deaths, and diphtheria 4. Whooping-cough was the cause of 48 deaths. One hundred and fourteen deaths were referred to convulsions. Bronchitis killed 247 persons, or 1 in every 7.6 of all the deaths. Forty-nine persons died from pneumonia. Phthisis numbered 277 victims, being in the proportion 1 in every 6.8 of all the deaths. Mesenteric disease was the cause of 33 deaths, hydrocephalus of 49, and scrofula of 14. Seventy-eight deaths were attributed to heart disease, 4 to pericarditis, and 9 to aneurism. Liver disease (unspecified) contributed 40 deaths, hepatitis 3, and jaundice 1. Twenty deaths were referred to kidney disease (unspecified), 12 to Bright's disease, 2 to diabetes, and a like number to stone. Thirty-four deaths resulted from accidents, 2 from homicide, and 3 from suicide.

THE next examination for the London Society of Apothecaries' Annual Prizes in Materia Medica and Pharmaceutical Chemistry, will be held on Wednesday, the 18th, and Friday, the 20th of October, at 10 a.m. The prizes consist of a gold medal and a silver medal, with a book.

A COMPLETE set of the works published by the New Sydenham Society will be displayed in the annual museum at Plymouth, during the meetings of the British Medical Association.

THE mortality in Paris amounted last week to 835, but only one case of a choleraic nature is reported.

THE annual meeting of the New Sydenham Society takes place to-morrow (Thursday) at Plymouth.

THE late Mr. Grote has bequeathed £6,000 for the endowment of a Chair of Mental Philosophy, in University College, London.

THE annual meeting (thirteenth) of the New Sydenham Society will be held at Plymouth, in the Royal Hotel, on Thursday morning, August 10th, at nine o'clock.

MR. CHARLES BROOK, of Enderley Hall, Leicestershire, opened last week, in person, a Convalescent Hospital in connection with the Huddersfield Infirmary, which he has built at a cost of £12,000, and which, together with an endowment of £18,000, he has handed over to the trustees of the infirmary for the poor of the town and neighbourhood.

### THE SMALL-POX IN LONDON.

ON Saturday last, at a meeting of the Metropolitan Asylums Board, Dr. Brewer, M.P., in the chair, the report of the Stockwell Asylums Committee was read. It stated that during the fortnight up to that day 113 fresh cases had been received at Stockwell; 215 persons had been discharged cured or sent to the Dreadnought Convalescent Ship, and 27 had died, leaving 285 then under treatment—namely, 176 in the fever asylum, and 109 in the small-pox asylum proper. Up to the present 2,908 cases had been treated in these hospitals, of whom 2,133 had been discharged and 470 had died, the average mortality being 16.8. It was with great satisfaction the committee reported that, during the week ending that day, the fresh cases admitted showed a marked decrease, being fully 40 per cent. less than the week before; and so many were the vacancies now caused by discharges and deaths that there were then 131 cases fewer than at the last report a fortnight since. The committee suggested that under these circumstances there should be a gradual discontinuance of the fever hospital for small-pox patients, and it was hoped that by the end of a few weeks the small-pox hospital by itself would give sufficient accommodation for the wants of the district assigned to the committee. The Homerton Asylum's Committee report stated that, since the last meeting there had been 79 admissions of fresh cases; 16 persons had died, and 26 had been discharged, leaving 150 now under treatment—103 in the small-pox hospital, and 47 in the fever hospital. During the same period 40 cases had been sent to the Board's other hospitals. In accordance with the resolution of the Board, steps had been taken for disinfecting the fever hospital, in order that it might be made ready for any fever cases which might arise in the metropolis. The medical report showed that of the 79 fresh admissions 46 were vaccinated and 33 were unvaccinated; and of the first class six had died, while of the unvaccinated ten had died. In all, up to the present time, 1,161 persons had been treated in the small-pox hospital of Homerton, of whom 682 were vaccinated and 479 unvaccinated. Of the vaccinated, 38 had died, while 164 unvaccinated had died. In the fever hospital since the opening, 1,194 cases had been treated; 772 vaccinated, and 472 unvaccinated. Of the larger number of protected cases, 35 had died, while 141 of the unprotected had succumbed. The proportions of deaths in all the hospitals under the Board showed like results in the large excess of mortality among the unvaccinated cases. The Hampstead Hospital report,

showed that there was a great decrease in the North London district in the epidemic. The Dreadnought Hospital report stated that 131 patients had been discharged from the ship since the last meeting and 110 had been received, making in all 156 in the ship at the present time.

### REPORT OF THE MEDICAL OFFICER OF THE PRIVY COUNCIL.

THE report of the Medical Officer to the Lords of Her Majesty's Most Honourable Privy Council has been published, but according to a practice against which we hereby protest, this journal has not been favoured with a copy. While stating this we may as well observe that these blue books are issued for the benefit of the public and ought to be impartially distributed. We beg to ask "the Lords of Her Majesty's Most Honourable Privy Council" whether it is with their sanction that some journals are favoured with early copies while others receive no copy at all?

The report states that the two epidemic diseases which in 1869 required particular attention from this department continued seriously prevalent in 1870—namely, that relapsing fever, which had scarcely excited much apprehension, except in London, where then it had begun to decline, afterwards increased very considerably in other of our great centres of population—particularly at Liverpool, and in a less degree, at Leeds and Merthyr-Tydfil; and that scarlatina, which also had begun to diminish in London after an epidemic of extreme severity, has till now continued ravaging other parts of England with its extraordinarily fatal prevalence. Besides these causes of anxiety in relation to the public health of 1870, there began early in the year signs of a recommencing ascendency of small-pox in England; and before the close of the year it had become evident that at least for the three and a quarter million inhabitants of the metropolis, the severity of this epidemic of small-pox would be beyond any recent experience we had had of the disease.

During the year 1870 there were 200 cases where communication with local authorities was necessary in regard of questions of common sanitary administration; and in sixty-six of these cases the communication involved local inquiry by a medical inspector of the department. Almost invariably the matter calling for inquiry was the local prevalence of some dangerous infectious disease.

As regards the sixty-six cases where it was practicable to send a departmental inspector to the locality, the conditions which in each case the inquirer found existing, were in no case satisfactory, and very rarely other than of the grossest local neglect.

It is next remarked:—The inadequacy of the present staff of this department to supervise the local administration of the Diseases Prevention and Nuisances Removal laws, and to meet (or even nearly to meet) by medical inspection the demands which are made by local outbreaks or apprehensions of dangerous infectious disease, became in 1870 extremely evident, as may here already have been inferred from the fact that inspectors visited only a third part of the number of cases where communication with local authorities was necessary.

In 1870, as in the previous years, this department superintended the public vaccination of England.

The report then refers to communications with the General Council of Medical Registration and Education on the subject of the working of the Medical Act.

As to the Pharmacy Act we read:—I regret to report to your Lordships that the power which, for the public protection, the first section of the Act vests in the Pharmaceutical Society, to prescribe (with consent of the Privy Council) regulations as to the keeping, dispensing, and selling of poisons, is still entirely unexercised. I believe it to have been by an accidental oversight in legislation, that, while all other powers to be exercised for public purposes by the Society under the Act were vested in the Council of the Society, the language of the first section vested in the Commonalty, and not in the Council, the very important power which that section confers, and to which my present observations relate. It is perhaps not surprising that a large body of tradesmen should be slow to take the initiative in imposing even the most reasonable penal restrictions on themselves; but I have to submit to your Lordships, as a fact which you may deem deserving the considera-

tion of Parliament that this non-fulfilment of the Society's duty, to make rules against dangerous slovenliness in the keeping, dispensing, and selling of poisons, is a breach of the implied contract under which the Legislature in 1865 gave powers and privileges to the Society.

At the present date, when, according to statute the departmental proceedings of 1870 must be reported, the proceedings from day to day are such as to leave little opportunity for retrospect. An epidemic of small-pox, greatly more severe than any in the last thirty years, is prevailing through this metropolis; while, at the same time, in virtue of an engagement made in the last Session of Parliament, a Select Committee of the House of Commons, appointed for the purpose, is taking evidence as to the working of the Vaccination Act of 1867, and as to the value of various objections which have been agitated against the practice of vaccination.

It is next said the unamed state of the sanitary laws, especially as regards the constitution of local authorities and the powers which they ought to have and exercise for the prevention of disease, is not only an extreme difficulty and discouragement to persons engaged in sanitary administration, but also involves a large and constantly-increasing waste of human life; and that since the resources which might be utilised for the better protection of life, are also with the progress of knowledge constantly increasing, so, almost month by month the contrast becomes more and more glaring between the little which is done, and the very much which with amended law might be done to reform the sanitary circumstances of the masses of our population.

The report estimates that the deaths which occur in this country are fully a third more numerous than they would be if our existing knowledge of the chief causes of disease were reasonably well applied throughout the country; that of deaths, which in this sense may be called preventible, the average yearly number in England and Wales is now about 120,000 and that, of the 120,000 cases of preventible suffering which thus in every year attain their final place in the death register, each unit represents a larger or smaller group of other cases in which preventible disease, not ending in death, though often of far-reaching ill effects on life, has been suffered. And while these vast quantities of needless animal suffering, if regarded merely as such, would be matter for indignant human protest, it further has to be remembered, as of legislative concern, that the physical strength of a people is an essential and main factor of national prosperity; that disease, so far as it affects the workers of the population, is in direct antagonism to industry; and that disease which affects the growing and reproductive parts of a population, must also in part be regarded as tending to deterioration of the race.

### CHLORAL HYDRATE.

MANY interesting observations respecting this substance continue to be made.

At a late meeting of the Medical Society of Albany, we find a discussion started by Dr. C. D. Mosher, who made the astonishing statement that he had lost a patient by using one grain.

Dr. Robertson has noticed distinct conjunctivitis following its use. In doses of from five to ten grains, for wakefulness it was very successful. In his own practice he had noticed a singular coldness following its use.

Dr. Hun stated that he had seen it used at the Insane Asylum at Utica in doses of forty grains every half hour with little effect. A private patient had taken forty grains per day for three months with no ill effect. He had never seen bad results from its use.

Dr. J. W. Moore had found it valuable in whooping-cough.

Dr. Beckett had a case of a woman who had been drinking excessively, and took by mistake, 5ij, at one time. She slept two hours then repeated the dose. She recovered in a few hours without experiencing any ill results.

Dr. J. S. Bailey had used it successfully in insomnia of children, had given a child one year old five grains with a happy result.

In the *Algen. Wien. Med. Zeit.*, of 27th June, Dr. Antoni

Holler gives some observations on the effect of chloral upon maniacs. In a maniac, Franz, he found a most useful effect from the employment of chloral. Sleep followed in a quarter of an hour after the drug was swallowed and continued sometimes eight hours without cessation, generally three hours. Without it the nights were generally sleepless. In the night of the 16th December, 1870, sleep lasted for ten hours. Chloral was not given on the following night, but the patient slept also eight hours, and on the night afterwards six hours. In the night of the 19th and 20th December, sleeplessness again supervened, and the patient was very restless, arose, cast off his bed clothes, was plagued by visions and noises, and endeavoured to cast out the threatening figures from the apartment, afterwards he had hallucinations of smell, gnashed his teeth, struck the wall with his fists as he saw figures there and spoke much of excrement. At seven in the evening he took a sixth of a grain of morphia, and, as he was no better from this, at eight and at nine he had a grain of morphia without the slightest sleep being produced. The excitement did not pass away. The patient felt as if his bed were on a swing and as if the wall of his room were falling in upon him; he therefore stood upright, sobbed, raged, and struck about him in all directions. It was not until two drachms of chloral had been taken that he had again a quiet sleep of nine and a half hours, which was followed by no mania. From this case it is clear that chloral had worked more certainly than the two one-sixth grains of morphia taken within two hours. The hypodermic injection of morphia could not be used partly on account of the restlessness of the patient, and partly because it had been tried before to the extent of a grain of morphia without effect. In January, 1871, with two drachms of chloral he had once sleep for ten hours; five times for eight hours; once for seven hours; five times for six hours; and once for five hours. In the month of February, 1871, he took morphia in doses of one-half, three-quarters, and one grain for a dose. The longest duration of sleep from morphia was, with one grain of morphia, nine hours. So far as this patient, Franz, was concerned, chloral was found to be a far more certain hypnotic than morphia, whether taken internally or subcutaneously injected. Neither of them had much effect when the patient was much excited or constipated. For three and a half months only twice did sleep fail to be produced by chloral, whilst with morphia it failed six times in thirty-six days. The working of chloral is consequently more certain than that of morphia and should be preferred as it causes no constipation or stupidity on awakening, so commonly seen with morphia.

Dr. George Elliott, of Hull, states that a patient of his, suffering from delirium tremens, took, in rather less than seventeen hours, 260 grains of chloral. A draught, containing 80 grains of chloral, was first ordered to be given in two parts, one half at midnight, and the second half—if sleep did not come on—an hour and a half subsequently. No effect followed. At eight o'clock the following morning 60 grains were administered, and sleep followed in a quarter of an hour and continued for two hours, pulse 120, feeble and small. At two o'clock 60 grains of chloral were again administered, and he being still sleepless, 60 additional grains were given between four and five o'clock.

The patient slept from five o'clock, but woke up occasionally during the night to take nourishment. The next day the pulse was 88, comparatively full and strong, and the patient quite rational and free from his complaint.

He had no vomiting for the last twenty-four hours of his illness, and during that time partook freely of Liebig's extract of beef, to which had been added whipped white of egg.

Dr. Robert Munro states his experience of chloral hydrate—as indicated by a number of cases appended—has led him to the following conclusions:—

*First.* Chloral hydrate is of great benefit in cases of mental excitement and functional disturbance of the

nervous system when there is no organic disease of the brain.

*Second.* Chloral hydrate is injurious in cases of protracted and great debility, more especially if the body is reduced by unnatural discharges.

*Third.* The long-continued use of chloral hydrate, even in small doses, is injurious under any circumstances.

*Cases.*—1. A draught containing 28 grains was given to a lady at ten p.m. Two hours afterwards summoned to see her, found her restless, much excited, with a quick pulse, and no tendency to sleep; then ordered the usual draught of morphia, and she soon fell asleep. Continuing the chloral for three nights consecutively, gradually increasing the dose each night, the same result followed, and it was discontinued.

2. A young man suffering from insanity, with great excitement and sleeplessness, caused by too much mental work, fell asleep after the administration of a half-drachm dose. This treatment was continued for three nights with the same good result, when he was removed to an asylum.

3. In two cases of chorea it produced sound and refreshing sleep, and was only required for a few nights.

4. In four cases of delirium tremens it acted as a charm in half-drachm doses, repeated every two hours, till sleep ensued.

5. In a case of pelvic cellulitis, about a week after the abscess was evacuated, on two trials it was followed by so much restlessness, sleeplessness, giddiness, and discomfort, that the patient positively declined to take it any longer.

6. In several cases of phthisis sooner or later it produced unfavourable symptoms.

7. For the sleeplessness due to age it was given to three patients, all upwards of eighty years of age, and in one only was it effective.

#### PROPYLAMIN IN RHEUMATISM.

DR. JOHN M. GASTON gives in the *Indiana Journ. of Medicine* the result of his experience for several years past in the use of *Propylamin*. It is about eleven years since this article was placed before the Profession as a remedy in rheumatism, on the recommendation of Prof. Arzenarius, of St. Petersburg; he treated with it successfully, between 1854 and 1856, 250 cases of rheumatism, acute and chronic, with all sorts of complications, metastatic, pericardial, pleuritic, meningeal, hemiplegic, and paraplegic, and all recovered.

Dr. Gaston's experience during the past eight years has accorded with that of the distinguished gentleman named above, so as to give him great confidence in its usefulness.

He says his experience of it has been confined to cases of acute rheumatism altogether—and so confident has he become of its powers that he has been in the habit for years, on first diagnosing a case of rheumatism, of promising relief in twenty-four or forty-eight hours.

He adds, "most cases of acute rheumatism are ushered in by chill, fever, and general disturbance, as well as pain. I usually see that the patient is in a proper condition for the use of the agent, his bowels not constipated. I sometimes order a cathartic, and I frequently premise its use by administering fifteen or twenty grains of quinine, in the first twenty-four hours to an adult, after which from two to six or eight drops of the liquid propylamin in a tablespoonful of water every two hours for the first twenty-four hours, and at longer intervals the next twenty-four hours, and the cure is accomplished, so far as relief from soreness of the joints and pain is concerned.

The propylamin is found in the shops in two forms, the liquid and the chloride, or muriate. The former is a colourless, transparent liquid, with a singular ammoniacal, and fish-brine odour; is soluble in water, and has an alkaline reaction, and in solution of two to ten drops in a teaspoonful of water is nearly tasteless, and is, so far as I have been able to learn, devoid of poisonous or injurious properties. Its chemical equivalent is  $C_6 H_9 N$ .

The chloride is in the form of white crystals, very soluble in water, one grain of which is equivalent in action to about one drop of the liquid.

The agent in either form is somewhat expensive, and that has perhaps been a hindrance to its general use. It formerly sold for five dollars an ounce in this city, but it is cheaper now, costing about three dollars per ounce. I imagine it is sometimes diluted as found in the stores, and if it should fail sometimes on trial, it might be well to bear that in remembrance, and increase the dose.

It is said to exist in cod-liver oil, in ergot, in chenopodium, and in sorghum, and is extracted from chemical opium and several other sources, but the most abundant source of its supply is found in herring-brine.

A very convenient formula for its administration is as follows:—

R Propylamin . . . 50 to 80 or 100 drops.

Distilled water . . . . . 8 oz.

M. S.—Dose, tablespoonful every two hours to adult.

## HOMŒOPATHY—ITS PRINCIPLES EXPLAINED.

(Continued from page 102).

### LECTURE II.

PROP No. 2.—“When a person is hot do we give him cold drinks? No, we give him warm.” After our lesson in natural philosophy we need not be surprised to learn one in physiology. It is quite new to us that to be hot after a walk or other exertion is “a diseased state,” and requires the “homœopathic cure.” We do not usually expose ourselves to extremes of temperature, as they are apt to produce too powerful a shock on the nerves. “When a person is frozen we use cold friction, &c.,” not that it is applying cold, but heat, as proved by the melting of the snow employed; besides every tyro knows that friction always develops heat. We rub with snow then because by that means we ensure a gradual return to the proper temperature of the body. In other words, we apply heat, an antipathic cure. We remove the cause and the effect then ceases. In all these cases Dr. Epps endeavours to catch the public by saying that the means used to prevent too sudden a reaction is applying the agent which caused the effect, but the fallacy is perfectly transparent. Is it surprising that the masterpiece of the Creator—the human frame, so “fearfully and wonderfully made,” cannot with impunity be exposed to the same annealing process to which things without life may submit; or that when, on the verge of death, he should be unable to sustain an increase of the cause without depriving homœopathy of a patient by his thus hastened and premeditated death?

Prop No. 3 to this falling structure is of rather extraordinary texture. We are told that the “Scriptures” give support to the theory of Hahnemann. Where? How? cries the wondering reader. “Why,” says Dr. Epps, “we are told to weep with those that weep and rejoice with those who rejoice.” We suppose that the poor Doctor really thinks he is rather elevating than degrading Scripture by such applications; but before he sets up for a tutor of Divinity let him learn the meaning of the words he quotes. If he insists on their being applicable to his present subject we must ask if weeping cures weeping? Was Mary’s sorrow for the death of Lazarus abated by Martha weeping with her? Were their tears dried up when “Jesus wept?” No! The weeping Saviour did not bring joy in his tears; but when the Omnipotent “came forth” removed the cause, then the effect did cease. Again, does rejoicing cure rejoicing? After Lazarus was raised was the joy of Mary removed by the joy of Martha, or hers by that of Jesus? Is the joy of the “Angels in the presence of God over one sinner that repenteth” subdued by the joy of the Church on Earth? These questions are quite sufficient to test the Doctor’s divinity.

Prop No. 4 is a series of cases which have been accidentally cured, and all of which Dr. Epps affirms are instances of homœopathic cures. He tells us that in all

these the medicines which cured were capable of producing the disease. Of this no proof is offered, but who would doubt the word of “John Epps, M.D.?”

In “Jahr’s Manual” some hundreds of symptoms are said to be produced by a dose of rhubarb, and any of the symptoms we are told it will cure. The same with other medicines. So many symptoms are said to be produced by all that it is scarcely possible to take anything which is not homœopathic to any disease. Rhubarb even produces incompatible symptoms, as diarrhoea and constipation!! If we tell them that a certain medicine cures a disease—Ah! say they, it produces it too. Bark was taken by the famous Andral without producing intermittent fever. The author of this trifle has taken it in small and large doses, and continued its use for a length of time. He has also given it frequently, but has never seen ague produced by its use. Mercury he declares to be of the same kind, but who would take mercury for salivation?

To crown all, he says, sulphur produces itch, but as that disease is dependent on a little insect burrowing beneath the skin, we must ask Dr. Epps how the sulphur makes the insect? Are we to adopt the notion that living matter springs spontaneously from the inorganic elements of the earth? But as no case has ever occurred in which the disease has been produced by the sulphur we need not trouble ourselves about the consequences to which such a doctrine would lead. “As a concluding illustration,” says the Doctor, “we may refer to the vaccine virus as protecting from small-pox. I have seen thousands who have been protected through life from small-pox, by the small quantity of vaccine virus introduced into their systems early in life. What is this but a disease, homœopathic to small-pox, preventing small-pox?”

In his book “On Counteraction,” Dr. Epps himself writes, “Vaccination is one of the most glorious exhibitions of the principles of counteraction.” Who shall decide when Dr. Epps disagrees both with himself and every body else. If vaccination were an instance of the homœopathic law, it ought to cure small-pox if given in the progress of that disease; but, alas! sad experience tells us this is not the case.

If any reader anxious to know what homœopathy is shall have waded thus far we hope he has now a clear idea of its theory. *Similia similibus*. Diseases are cured by the administration of medicines which produce the disease in question. But it must have struck the reader that in many cases, where cures cannot be denied, Dr. Epps admits the use of the proper remedy although he gives it on different principles. All are agreed then as to the remedy, but here the homœopath insists that his infinitesimal doses, after trituration, dilution, and infinite division are equal to the ordinary doses. This then introduces us to the practical part in the administration of drugs,—infinitesimal doses. But before he speaks of these we must hear his denunciations against the “uncertainty” of medical science. No one expects that cures are to be effected with mathematical certainty, or that life may be prolonged to an indefinite period; but onward is our watchword and onward are we going every day. Vast improvements have been effected since the days of the writers he quotes, and the coming age will be crowned with even greater triumphs. He complains that medical booksellers are loaded with useless accumulations, but may not the same be said of theology or almost any science. It surely is not so difficult to find out the grain as it is to get at the real germ of homœopathic writings. What has Dr. Epps to complain of when he has brought us thus far in order to explain his doctrine, and that we have had to follow him thus far to get an enunciation of his theory, which might have been given in a few words, and now he is about to enter upon the practical part of the subject or infinitesimal doses.

Having devoted half a dozen pages to becalling medical men and their science, he says imperatively “homœopathy establishes certainty.” A change certainly this. It surely

must be the certainty of doing no good if his theory were established; for no drugs or combinations of them will produce many diseases. Will chamomile, ipecacuanha, arsenic, &c., singly, alternatively, or in combination, produce cholera? Yet these are the remedies recommended for that plague in his "Domestic Homœopathy." In this work he also says the above remedies are to be frequently repeated, but such practice Hahnemann denounces. By looking at any of their books we see the theory refuted. Will mercury or liver of sulphur produce whitlow? Arnica or belladonna boils? Carbonate of lime or rhus warts? Flint, arnica, or antimony corns? In giving these do homœopaths respect their theory? As a concluding illustration, does vaccination produce small-pox? He next abuses physicians for prescribing more than one thing at a time, as he asserts one is sure to prevent the action of the other. This is strange, too, as he himself uses opium which contains more than six different substances. Why does he not refuse to use any but chemical elements? Perhaps because the trituration required would alter their chemical composition. Physicians have sufficient experience not to limit themselves to such absurd doctrines on the word of Dr. Epps who loves to go in opposition to the experience of all ages.

Our authority thus concludes his lecture—"Taking homœopathy thus into consideration I hope you will agree with me that homœopathy is a noble system." (*Sic*—If its doctrines are so untenable, is it not rather an *ig*-noble superstition raised on no foundation?) "That it is an addition to the healing art." (An addition without an improvement!!) "That it establishes certainty where uncertainty hitherto prevailed." (A certainty no doubt of its doing no good, and a certainty of its falseness.) "That it presents the quickest, the safest, the most agreeable way of curing disease." (It may, perhaps, be said that it is established that it cannot cure at all; so that it would be quite premature to reckon the time, the safety, or pleasantness of a cure which cannot be effected.) "And that as such it is worthy of steady support." (The reasons for its support being exploded of course no one can ask for support for such a cause. It is fit for nothing but to be cast among the heaps of useless rubbish that have emanated from infatuated minds, and only been supported by those who are easily duped or quickly carried away by novelty and wild enthusiasm.)

(To be continued.)

## Literature.

### MEDICAL AND SURGICAL REPORTS OF BOSTON CITY HOSPITAL.

THE preface to this excellent and most elaborate volume which space forbade us noticing before, tells its intention, as the hospital staff was entrusted with "the preparation of an enlarged and consolidated report which might be of general interest to the Medical Profession."

We may, without any hesitation, say that no more creditable report has perhaps ever issued from any hospital. The style in which it has been brought out, and the excellence of the illustrations, are beyond praise, and make it a standard volume with facts and statistics of an all important nature and of exceeding interest.

The chapter on the excision of joints is one full of information; the photographs are excellent, and confirm in the strongest way the advanced views which have been carried out on the treatment of this important class of disease.

Speaking of the success of the excision of the head of the thigh bone in diseased hip the following sensible and plain observation is made—"In this operation we imitate on a larger scale what Nature strives for: we expediate her processes; we make a large free and single opening in

place of several tortuous sinuses, and we get rid at once of the carious head of the femur. We thus shorten the period of invalidism in poverty, and assure the child a better hope of recovery." The latter is in a surgical point the point of interest which is borne out by the statistics given, and illustrated by excellent illustrations.

Nine cases of excision in children are given as occurring in the hospital; of these only two died—one of tubercular meningitis and one of tubercle; while in two adults where excision was performed death resulted.

Four cases of excision of the elbow-joint for caries were all successful.

Remarkable cases of perinephretic abscesses are also recorded, some of them having attained a very large size. The seton treatment was found the most successful, and far superior to either simple puncture or the use of the trocar.

Cases of cut throat, involving the pneumo-gastric nerve and subsequent ligature of the carotid artery, in a total of fourteen cases five died.

The question of tracheotomy is fully illustrated specially as to its utility in cases of croup. Out of nine cases where the operation was performed in the latter disease, the mortality was fifty-five and five-elevenths per cent., "a result although covering a small number of cases, so far as it goes, excellent."

The important and debated question of trephining the spine in cases of fracture, five of displacement and fracture are recorded, in two of which trephining was performed—one with restoration of motion and sensation, but death followed in twenty-four hours after the accident; in another instance death occurred nine hours after operation. The pressure was found to be caused by the body of the displaced vertebra—thus illustrating the question which has been discussed at the Surgical Society of Ireland as to the uncertainty of operative interference.

Amputations, fractures, lithotomy, and œsophagotomy are illustrated by remarkable and instructive cases.

The medical department of the hospital is also fully represented, and most interesting records are given. The alkaline and non-alkaline treatment of acute rheumatism are contrasted, and tables given of cases treated by each. The histories and treatment of 190 cases of pneumonia are of import, and illustrate the effects of varied treatment.

The illustrations of skin diseases are well and accurately represented—selected from over 1,000 cases.

A large space is devoted to the subject of peri-uterine inflammation, and this difficult and obscure subject is well discussed.

The ophthalmic and aural departments are equally interesting; 206 cases of cataract extractions with but nineteen unsuccessful results are tabulated.

The entire volume is full of information, as carefully recorded cases, with the history of the results of operative or medical aid are the essentials necessary to our laying down rules for guidance in difficult or urgent cases.

We congratulate the medical staff on the complete success of their report. It is elaborate, accurate, and most instructive; and we must also congratulate the trustees of the hospital on their happy initiation of a step in the right direction, in giving to the Profession and to the community a faithful and instructive record of the immense benefits conferred by an institution conducted with such vigour, efficacy, and talent.

### ON SPERMATORRHOEA.\*

It appears that seven large editions of this work have appeared and been disposed of. Some illustrations are added to this edition. In the preface, the author says that one of the best practitioners of modern days, Sir Benjamin Brodie, tells us that, the discrepancies between

\* "On Spermatorrhœa, its Results, and Complications." By J. Milton, M.R.C.S. London: R. Hardwicke. 1871. Pp. 114.

the systems of pathologists and the experience of surgeons would be avoided if writers would sometimes condescend to treat symptoms rather than diseases. This work is divided into three chapters. The first chapter treats of "Spermatorrhœa, its Results, and Complications," the second of the "Pathology," and the third, of the "Treatment of the Disease." There is but little history of the disease. That of gonorrhœa and syphilis is obscure enough, but compared with the darkness resting on spermatorrhœa, before the days of Hunter, it is light itself. Hippocrates describes the disease, and treats it by advising abstinence from drinking, venereal excesses and excessive exercise for a year. Celsus, in his work *de medicinâ*, lib iv, c. 21, says there is a disease of the genitals, which without nocturnal emissions destroys the patient by wasting. That author recommends cold swimming baths and affusions on the parts in such cases. After the Christian Era, the spiritual religionists kept the disease quite out of sight. John Hunter, in 1810, in his treatise on the "Venereal Disease," page 220 recommended cold baths and laudanum. Sir Everard Home first recommended the topical application of nitrate of silver. Lallemand, Curling, and Philip, have written luminously on the subject and also Acton. Lallemand's work is quite classical. In this department of practical medicine, as Mr. Milton truly says, "the present state of opinion about spermatorrhœa, both in the profession and among the public is unsatisfactory." Silly drivelling, like that made use of by writers that are praised by the editor of the *Medical Times and Gazette*, passes current in such matters. As Mr. Milton says, when a patient is afflicted with involuntary seminal emissions, and writes to the medical journals, he is counselled to consult his ordinary medical adviser, which is equivalent to telling him not to mind whether he is ill or not, since many doctors cannot abide even talking about such infirmities except in a high and contemptuous tone.

"That the disease (says Mr. Milton) exists to a very great extent, far greater than is generally thought; that it yearly reduces hundreds, if not thousands to impotence, and its attendant ills, hypochondria, weariness of life, insanity, and so on; that not only every town, but every village, could show victims to this neglected malady, are facts which I feel assured will not be disputed by those who have looked into the subject." We quite agree with this, and may remark *en passant*, that early marriage seems if possible, to be the great remedy for such a state of matters. "The observation (says our author), has been more than once made in medical papers, that one emission once a week or so can do no harm, and although this may hold good of a short period in early life, it becomes a very dangerous tenet when applied, as in the nature of things it will almost certainly be, to long standing cases and a more mature age, &c." The disease often taxes all the practitioner's resources. The disorder is divided by him into nocturnal and diurnal emissions. Dr. Albas, of Bonn, says that in some cases, there is merely abnormal discharge of semen, in others there is morbid change in the seminal vessels and in the urethra and prostate. When not severe, nocturnal emissions require only cold bathing, exercise out of doors and tonics. In men after twenty-three or so, more than one emission a month deserves attention, according to Mr. Milton. Diurnal emissions are not very common, but some persons have them on the least excitement, or shaking in railway carriages may produce them. Mr. Milton rightly we think, assigns much more importance to the nervous exhaustion than to the waste of semen in emissions, and quotes from the *M. Chir. Rev.*, 1864, that, "masturbation shows its ill consequences in the female almost equally as much as in the male, though no exhaustive discharge be induced." Dr. Humphry, of Cambridge, too, considers the commonly received opinion, that the debility is due chiefly to the loss of spermatic fluid, to be a mistake. Delicate persons, perhaps, are more inclined to emissions, but strong men sometimes suffer much from them. In training men, it is usual to discard those who suffer from frequent wet

dreams. The symptoms of the disease are weakness, want of energy of mind, pains in the loins, pain at occiput, neuralgia of head or face, dyspepsia, unhealthy sleep, palpitation of the heart, breathlessness, epilepsy, paralysis, and amaurosis, with insanity make up the list. We quite agree with the prognosis given by the author, that in young persons under thirty, when erections are still good there is every reason to hope for a cure, whilst when emissions are always frequent, it is a very difficult matter to cure the disease. We quite agree with him, that Mr. Acton is too sanguine as to curing spermatorrhœa in some cases. Some cases are hopeless. Stricture of the urethra sometimes causes impotence, and when removed, the malady disappears like magic. Mr. Milton says, "a man who remains continent, can hardly reach twenty-six without becoming partially, if not wholly impotent. I am not quite certain that he is safe at twenty-four." This observation is directly opposed to that of Mr. Acton. Patients with spermatorrhœa are ever sensitive to cold. Long continued, steadily increasing impotence from excess, must be regarded in a very unfavourable light, especially if the patient has passed his thirty-fifth year. As to discharges of mucus at stool, Mr. Milton thinks they are never almost seminal, *i.e.*, they do not contain spermatic filaments. It is the testicle which is concerned in the effects seen in spermatorrhœa, not the seminal vesicles at all, says the author. Spermatozooids in the urine are not to be looked on as always a sign of disease, indeed our author tells us that, Mr. Queckett, had frequently examined the urine in bad cases of spermatorrhœa and had rarely met with them.

M. Liègeois, of Paris, says that all healthy men of all ages have spermatozooids in their semen, although in old persons acute chronic diseases seem frequently to make them disappear. Double orchitis when from gonorrhœa almost always causes azoospermia, and syphilitic orchitis often does so. Spermatorrhœa as a rule, does not modify the spermatic secretion. Quinine is, according to Mr. Milton, of great use in spermatorrhœa in some cases. Tincture of sesquichloride of iron also at first in doses of twenty or thirty minims twice a day. Many persons can take a drachm and a-half thrice a day. The liquor ferri perchloridi of the *British Pharmacopœia* may be used, measured by minim glass. Ergot of rye is not much esteemed by Mr. Milton in emissions, although it is much liked in America. We have also found it useful. Camphor is, our author says, useful after gonorrhœa in doses of one drachm of the spirit of camphor occasionally. Lupulin in doses of five grains may be tried. Digitalin, in doses of the fiftieth of a grain has been praised. Opium is very useful in many cases in doses of fifteen drops of Batley's solution, and J. Hunter approved much of it at bed-time in emissions. Chloral hydrate Mr. Milton does not like, and belladonna is also unpopular with him. Bromide of potassium he is disposed to look on with favour, when there is much excitement and sleeplessness, in doses of a scruple to half a drachm. Aperients are sometimes useful when dyspepsia exists. Strychnia in doses of a twentieth of a grain in a pill at bed-time is useful. Diuretics, such as nitre are sometimes useful. Copaiba is hurtful. So much for the use of drugs. The genitals should be daily bathed with cold water from a large sponge, squeezed, at the upper part of the abdomen, over the genital organs. Ice cold water is useful. Cold water baths should be used when the patient feels stronger after them. The patient should sleep as cool as possible, with the windows open in summer or winter. Mr. Milton justly condemns the plan recommended by M. Trousseau, of compressing the seminal vesicles by means of a plug in the rectum, but approves of a leather ring fitted around the penis, with steel points internally, which prick the organ when it becomes erect and thus waken the patient. An electric alarm has also been devised for this purpose. Blistering the penis and perineum is sometimes very useful by means of Bullin's blistering fluid. Mr. Milton sometimes uses topical cautery to the urethra, but says it

is not often called for. Mr. Curling says it is not infallible; Lallemand used it for twenty years, and Mr. Curling had not seen any injury arise from it. Others, however, have seen bleeding, stricture, &c., to follow from this remedy. Many persons of experience have almost abandoned the use of cauterisation. Injections are much superior to cauterisation, and Mr. Milton likes nitrate of silver but not stronger than twenty grains to the ounce. The urethral tube is passed as far as the membranous part of the urethra, and then two drachms of the solution thrown in. The diet in spermatorrhœa should be plain and nourishing, low diet is bad. Patients should eat plenty of meat so as to keep them in good health. Heavy suppers are to be avoided. Claret seems to agree with many patients, spirits should be avoided. The "abuse of smoking is bad." What is the use of smoking? The use of exercise is recommended. Dumb-bells for half-an-hour in the morning, or walking exercise in the open air; but violent exercise is bad. Close mental applications as recommended by Carpenter, is out of the question in bad cases of nocturnal emissions. Marriage should follow, not precede a cure of the disease, according to our author. Well, we suspect that, if marriage were universal, spermatorrhœa would not be the common disease it is at present. Gonorrhœa and gleet, and stricture must be cured. Varicocele treated with a scrotal ring. In impotence, quinine should be tried and strychnia, or the thirtieth of a grain of phosphorus in suet may be used occasionally. Ergot of rye. We might add the interrupted galvanic current. Mr. Milton's book is full of hints, evidently written by a man who has had bad cases to treat.

#### THE ANTISEPTIC SYSTEM.\*

THIS is a valuable contribution to antiseptic literature. It displays much industry and research, and forms an exhaustive exposition of what has been said in praise of carbolic acid in its germicide aspect, as well as an interesting statement of the claims of the germ theory of disease. Many adherents of the "antiseptic system" will, however, be disappointed that Dr. Sansom has allowed his marked predilection for carbolic acid to prevent him doing justice to other agents of the same kind. It will probably be thought that in a book of 350 pages, whereof 198 are devoted to carbolic acid, ten pages are somewhat too scant a space to give to all other antiseptics, especially when it is considered that the antiseptic system is not necessarily bound up with carbolic acid. That system was extensively and successfully practised many years before carbolic acid was even heard of outside the strictly chemical world, and has continued to be used and publicly recommended by several eminent surgeons, among whom may be named Mr. Campbell De Morgan and Dr. W. Smart, R.N., who rely on a totally different antiseptic, namely, chloride of zinc. This substance, under the name of Burnett's Fluid, was long the reigning disinfectant and especially in the Royal Navy, where its inventor and manufacturer, Sir William Burnett, was for many years Medical Director General. "Its antiseptic properties," to use the words of one of Dr. Smart's communications on the subject to the Medical press, "have been appreciated and relied on by naval surgeons through the last thirty years, especially in the treatment of sloughing ulcer, owing to its having been, until recently, the only disinfectant and antiseptic supplied from naval stores. Having had much experience of its use in gun-shot wounds," he continues, "after the plan recommended by Mr. De Morgan, I can state that I entirely agree with him on its great value, and I may add that I also have returned to it after the use of other antiseptics." "With no more care than this," Mr. Campbell De Morgan had previously written of the same agent, "I have had rapid cure without suppuration in crushed and lacerated wounds; perfect union by first intention in large operations, as high amputations of the thigh, etc.; and, very generally, union with only slight suppuration in the course of the wound, and this where ligatures have been placed on all the vessels requiring them." In the short chapter wherein

various antiseptic substances are touched on, Dr. Sansom himself has even admitted—unintentionally, perhaps, but very distinctly—the superiority in surgical practice of chloride of zinc over carbolic acid (pp. 256, 257), and that irrespective of its principal advantage, namely complete want of smell. He does not, however, seem in the smallest degree impressed with what he is obliged to say in favour of chloride of zinc, and goes on to speak of carbolic acid, as if it alone were truly possessed of antiseptic properties. Can it be possible that the sulpho-carbolates have, to some extent, to answer for this indifference to the claims of the great Naval antiseptic?

There are other adherents of the antiseptic system who will be hardly less disappointed with Dr. Sansom's attempt to represent that system as dependent on the germ theory of disease. The two things are quite independent one of the other. If the "antiseptic system" be the remarkably successful one which its advocates assert, its success is not necessarily bound up with the truth of the "germ theory," which is only one of several ways of accounting for the asserted success. Many good observers find a more satisfactory explanation in the property of coagulating albumen which all antiseptics possess—carbolic acid and chloride of zinc in an eminent degree. One of the latest experimenters on the subject, Dr. Mackintosh, of Callington, has arrived at the conclusion that the complicated plans of dressing wounds which have been contrived by Professor Lister, for the purpose of "poisoning the germs," are totally unnecessary, the beneficial effects of carbolic acid being principally due to its direct salutary influence on the parts concerned.

To certain, and not a few minds, there seems so much satisfaction experienced by being able to connect any phenomenon with individual vitality, whether in the shape of spirit, ghost, germ, or parasite, that it may be doubted whether, on it being distinctly proved to such that the "antiseptic system" was the most successful hitherto practised, but not by reason of its influence on "germs," they would not immediately lose all interest therein, and abandon it as unsatisfactory. The charm of doing battle, as it were with personal entities, and of lying in wait for and poisoning the sneaking parasites, would be gone. It may, we think, be fairly asked,—Would Dr. Sansom have taken the trouble to write at such length on the antiseptic system minus the sensational germs? When we look at the 123 pages which have been devoted to them in one connection or another, we feel we should be warranted in saying that he would not.

We have all the less hesitation in answering this query negatively, because it seems so evident to us that it was in this part of his work that the author felt most interest, as it is also the one on which he has written best. The chapter entitled "The Zymotic Theory," and the two on *materies morbi* are very meritorious. They contain an instructive classification of the spreading diseases, and furnish a very complete view of the various theories explanatory of their origin,—put, of course, so as to lead up, as far as possible, to the author's particular opinions. Nevertheless, we venture to say that there is something eminently unsatisfactory about them, as about most chapters written in advocacy of the "germ theory." They are characterised by studied vagueness of language, and the use of a multiplicity of quasi-synonymous phrases, which by inuendo are made to suggest a great deal more than they express, but are ever carefully kept from plainly uttering the thing really intended to be taught, namely, the parasitic origin of the spreading diseases. Only when passing in review some of the facts connected with the universally recognised parasitic diseases, such as scabies, trichiniasis, &c., is the word parasite permitted to escape. Instead, we find a profuse use of the following expressions:—organised material, minute particles of bioplasm, organised molecules, living matter, vitalised molecules, matter possessing vital endowments, particles possessing life, living germs, &c. These various forms of speech are apparently employed for the purpose of familiarising the reader with the statement that infective material is possessed of vitality, and in the hope that he may come unconsciously to recognise it to be composed of "minute living organisms."

The latter expression does not, however, occur in the body of the work, wherein nothing approaching to it in distinctness of enunciation of the real doctrine inculcated is to be met with; it occurs in the preface, where the author has thought fit, at last, to avow parasitism, but not without a final effort to envelope the avowal in haze. "The poisons of the spreading diseases," he there writes, "are extremely *minute living*

\* "The Antiseptic System; a Treatise on Carbolic Acid and its Compounds." By Arthur Ernest Sansom, M.D., etc. London: Henry Gillman, 1871.

organisms, having the characteristic endowments of vegetable growths, owing their specific properties in the special diseases not to any botanical peculiarities, but to the characters implanted in them by the soil from which they first sprang from innocuous parents, and from which they are transmitted—this soil (except in the case of their earliest origin) being the fluids of the animal body." (Preface, p. x.) It was, perhaps, natural that Dr. Sansom should shrink from putting forward his statements about vitalised molecules as premises whereby to establish the above vaguely formulated fungus-germ theory. Vitalised molecules, organised material, particles of bioplasm *et hoc genus omne*, are blood products, whereas "minute living organisms, having the characteristic endowments of vegetable growths," must be extraneous bodies, and not blood products. These two categories of material are diametrically opposed to one another. No wonder, then, that our author, after—in the body of his work—firmly establishing, to his satisfaction, the vitalised molecules, could not see his way openly to use them in the sequel for the support of independent fungus particles. By throwing the conclusion into the preface, logic was less glaringly violated, and the transformation of bioplasm into vegetable organism was accomplished, as it were, between the acts and after the descent of the curtain.

The observations which have afforded Dr. Sansom the strongest arguments in favour of the "germ theory," seem to be those of Hallier, relating to the so-called cholera fungus, and those of Pasteur and others, whereby the extensive prevalence of parasitic fungi in diseased silkworms has been proved. But the elaborate official report of Dr. T. R. Lewis, on the microscopic objects found in cholera evacuations, made by order of the Government of India, has completely exploded the hasty generalisations of Hallier, and relegated his cholera fungi to the category of inoffensive and commonly prevalent "smuts." Dr. Lewis's conclusions may thus be summed up:—1. No cysts exist in choleraic discharges which are not found under other conditions. 2. Sporangia of fungi are very rarely found under any circumstances in alvine discharges. 3. No special fungus has been developed in choleraic evacuations, the fungus described by Hallier being certainly not confined to such. 4. There are no fungoid developments, either as to nature or proportionate amount peculiar to cholera, the same organisms being developed in nitrogenous materials outside the body. As to the silkworm disease, recent investigations into its nature, instead of affording support to the fungus theory all tend the other way. Silkworms affected by the disease are found, it is true, to be completely saturated with a certain fungus. But it has been shown by M. Guéruin Menneville that the real source of the malady lies in the food of the insects, namely, the mulberry leaves. By comparative analyses of dry mulberry leaves, procured in countries where the disease is not known or almost so, and of others obtained from the mulberry gardens of France, Dr. E. Reichenbach has quite recently demonstrated that the latter have become impoverished to a remarkable extent of nitrogen. The deterioration of European mulberry leaves is, according to Dr. Reichenbach, traceable to faulty agriculture, which has neglected to supply nitrogenous manure to the trees, whereas in Eastern Asia that necessary plant-food has been carefully provided in the routine culture. It was, therefore, truly in vain that Pasteur and others devoted so much time to exhibit, by means of the microscope, the existence of fungi and their spores in diseased silkworms. No light whatever was thereby thrown on the source of the malady. The evil is one of nutrition, and can only be remedied by an intelligent culture of the tree which produces the insects' food. Here is a splendid justification of the teaching of Liebig. It is to the scientific application of the chemical principles of nutrition, as taught by that great master, and not to the microscopic appearances presented by the diseased structures, as triumphantly exhibited by Pasteur, that we can alone look with hope for that which will guide us, in the choice of measures for restoring to health and vigour the artificially vitiated constitution of the silkworm in Europe.

Whatever may be thought of the originality of Professor Tyndall's experimentalisations on "dust and disease," and of the cogency of his argumentations on the "germ theory," his utterances are at all events to be commended for their frank avowal of parasitism. In his latest lectures at the Royal Institution, that distinguished physicist has plainly stated his adhesion to the theory that "contagious diseases generally are of a parasitic character." He, too, supports this notion by reference to the case of the silkworms of France, adding that "it is in the highest degree important to know whether

the parasites in question are spontaneously developed, or are wafted from without to those afflicted with the disease; the means of prevention if not of cure being widely different in the two cases." But it is not very many years since the now prevalent silkworm disease, which is still absent from the original seats of sericulture, was also unknown in Europe. If its rise was due to the wafting from without of fungus germs, where did the wafting begin? Certainly not in the East, where the disease does not yet prevail. On the contrary, the wafting has been all the other way, namely, from west to east. It follows that the distemper originated in the West, where, nevertheless, at an antecedent period, it was unknown. It cannot, therefore, have been wafted from without, but must have been developed within. We have seen the cause of this development, for which neither prevention nor cure can be expected to come from following up the false scent, whereon the public and a considerable portion of the medical Profession have allowed themselves to be put, by the hasty generalisations of certain enthusiasts, whose mental idiosyncrasies lead them to give a kind of fetish credence to the causal agency of individual entities, whether accordion-playing spirits, well-clad ghosts, or ubiquitous and Protean germs.

It was, of course, hardly to be expected that so thoroughgoing an antiseptist as Dr. Sansom, in the course of his disquisitions on infection and disinfection, should say much to remind his readers that nature somehow or other manages to maintain the purity of soil, water, and air by simple oxygen. Not a single expression to that effect has been let drop by him. Oxygen is neither a direct germ-poison, nor a retarder of decomposition. But, in its character of burner-up of the decaying matter in which parasites revel, and chief link between the organic and inorganic kingdoms, it is infinitely more precious. We have an impression that whatever real progress is to be made in the art of combating the effects of putrefaction and infection, must come from the close study of the processes of natural purification. Those processes, in which oxygen plays the first part, happily go on unceasingly, without respect to the lenses of microscopists, the retorts of carbolic acid manufacturers, and the lucubrations of antiseptic compounders.

## Correspondence.

### CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

THE following was forwarded to the Editor of the *Lancet* in reply to an "annotation," the writer of which stated that diseased women would not apply to hospital for treatment, and that moreover they often did not know when they were diseased:—

To the Editor of the *Lancet*.

SIR,—With regard to your assumption last week respecting the Contagious Diseases Acts, it is certainly true that a woman may be diseased without knowing it, but it is equally true that surgeons constantly fail to detect venereal maladies even when examinations are made expressly for their discovery. No fact in medicine or surgery can be better established than this. I need scarcely quote authorities, but may mention that Lancereaux, in common with other eminent authorities, recommends that the women should be examined at least every other day, and be shut up for several hours prior to introspection and watched. He then advises that the mouth, throat, and *anus* should be carefully looked into and the stripped skin examined, and adds that after all the smallest possible security is ever obtained. No one can deny that the presumption that a woman has been examined and reported healthy is a great temptation to men inclined to indulge, and then we have clandestine prostitution with its accompanying concealment and avoidance of treatment of disease. Moreover, as Mr. Evans has remarked, the condition that communicates syphilis is to be known not by examination but by its effects; and though a woman may be diseased without knowing it, if she is a prostitute she will very soon discover the fact, because her paramours accuse, insult, and often beat her for contaminating them.

It is contrary to human nature, and common sense to suppose that under such circumstances she would not apply to any hospital where she would be kindly received, and kindly treated and restricted as little as possible.

I think it is great mistake to make these hospitals prisons as is done under the Contagious Diseases Acts, although in spite of this deterrent (although the writer of the "Annotation" in question appears to be unaware of the fact) there is abundant evidence to show that diseased women gladly avail themselves of hospital accommodation. Mr. J. R. Lane, Leonard Woolcombe, Skey, Holmes, Coote, Paget, Whyatt, all give evidence to this effect; and in page 10 of the "Blue Book," containing the report of the Lords' Committee, I find the following—"It has been amply shown by evidence before the Committee that the Act tends to lessen its success by inducing diseased prostitutes to flock into the places where it is in operation, in order to gain the benefit of treatment in the hospital." There is also sufficient evidence to show that by a little management they are readily induced to remain under treatment until they are cured.

I am, Sir, your obedient servant,

CHAS. BELL TAYLOR, M.D., F.R.C.S.E.

The following was forwarded to the Editor of the *Lancet* in reply to a letter by Mr. Holton.

To the Editor of the *Lancet*.

SIR,—Permit me through the medium of your columns to thank Mr. Holton for the very conclusive proof which he has afforded us as to the superior efficacy of voluntary Lock hospitals as compared with the system embodied in the Contagious Diseases Acts. Mr. Holton says that—"The number of admissions into hospital in the 77th Regiment in 1861 was 534; by the intervention of a Female Lock hospital and the carrying out the principle of these Acts in a very imperfect manner the admissions in 1862 were 124. In 1863, on going to a station where a Lock hospital could not be managed, the admissions were 878." This is very satisfactory evidence that Lock hospitals without the intervention of police spies or forcible introspection of supposed prostitutes, accomplish all that could be expected or desired, and, indeed, infinitely more than vain aggravating efforts at police control. It is clearly incumbent on the promoters of these laws to show—

- 1st. That there is a necessity for exceptional measures.
- 2nd. That the means proposed are almost certain to succeed.
- 3rd. That no less disgusting measures would suffice.

Mr. Holton says that "The intervention of the Acts is unnecessary," owing to the good effected by female Lock hospitals, and such efforts as the women themselves make to avoid infection. They are therefore unnecessary, and the Sanitary Commissioner of the Punjab, Surgeon De Renzy, has shown by facts not to be controverted that the Contagious Diseases Acts have utterly failed to attain the end in view. He says: "Notwithstanding these Acts there is nowhere any substantial improvement in the condition of the troops as regards venereal disease, for twenty years ago these maladies were not more frequent than they are now." Two months ago the Magistrates' Council in Bombay declined to vote the money necessary to carry out the Contagious Diseases Acts in that Presidency, so disgusted were they with the whole measure; and the *Indian Public Opinion*, of November 15, 1870, says: "The plea for saddling the ratepayers with any expense for this fancy scientific purpose was based on the scientific assumption that the measure would be at least effectual in checking disease, whereas it has, in fact, proved a most notorious failure." A similar paragraph appeared some months ago in the *Mutras Times*; and on the commencement of the agitation several Indian officers, including some leading men, sent a considerable sum of money to the Ladies' Association for obtaining Repeal. Similar evidence has been forwarded from Cape Town where already a powerful association with the Bishop and other important residents for members has been formed for repeal.

I am Sir, your obedient servant,

CHARLES BELL TAYLOR, M.D.

P.S.—Scarlet fever creates more devastation in one year than syphilis in twenty.

## Medical News.

**Royal College of Surgeons in Ireland.**—At the quarterly examination held on July 22nd, 24th, 25th, 26th, and 27th, the following gentlemen obtained the licence to practise Surgery:—John G. Allen, Frederick A. Bernardo, Robert Bernal, John N. Bredin, Thomas H. Browne, Thomas Drapes, Henry E. Evans, Christopher Fleming, Michael Fitzgerald, Otho Galgey, Francis B. Hannan, James A. Hanrahan, Richard Henry, Henry Heyward, Andrew Irwin, John C. Lawrenson, Edmond A. Lucas, Christopher MacNally, Ayres Moore, Herbert M. Nash, James S. Niven, Richard W. O'Donnell, Nicholas S. O'Farrell, William H. Ovenden, George A. Raverty, Stephen Raverty, Laurence J. Ryan, Harvie Scott, William A. Sharpe, Philip H. Skerrett, Hayman Thornhill, Charles P. Turner, Frederick W. Warren, Patrick S. Wignmore.

**The University of Edinburgh.**—On Tuesday week, the usual ceremony of capping medical graduates of the University of Edinburgh at the close of the Summer Session was held in the Music-hall, the Chancellor presiding. There was a large attendance. In the course of the proceedings the degree of Doctor of Laws was conferred on the following gentlemen:—Professor Andrews, Belfast; Professor Beneden, Louvain; Dr. Carpenter (Registrar of the University of London), Professor Challis, Anguste Colding, James Prescott Joule, James Joseph Sylvester, George Gabriel Stocks (Secretary of the Royal Society), Professor Allen Thomson (Glasgow), W. Spottiswoode (Treasurer of the Royal Society and of the British Association), G. E. Paget, William Huggins, M. Jules Janssen (Paris), and Peter Gassiot.

A curious defence was offered before the Sheriff of Glasgow in an action for breach of promise which came before him on Tuesday. At a previous court it was stated for the defendant that he had heard the plaintiff was affected with a skin ailment, which justified him in his refusal, and a remit was granted to Dr. McGill to examine the pursuer. He did so, and reported that she was not so affected; but that she was in good health. Pursuer, on hearing this report, said he was willing to marry the defender, but the latter objected, and the Sheriff gave her a decree.

**Instruction for Vaccinators under Contract.**—Revise "Instructions to Vaccinators under Contract," issued by order of the Lords of her Majesty's Privy Council:—1. Except so far as any immediate danger of small-pox may require, vaccinate only subjects who are in good health. As regards infants, ascertain that there is not any febrile state, nor any irritation of the bowels, nor any unhealthy state of skin; especially no chafing or eczema behind the ears, or in the groin, or elsewhere in folds of skin. Do not, except of necessity, vaccinate in cases where there has been recent exposure to the infection of measles or scarlatina, nor where erysipelas is prevailing in or about the place of residence. 2. In all ordinary cases of primary vaccination, if you vaccinate by separate punctures, make such punctures as will produce at least four separate good-sized vesicles, not less than half an inch from one another; or, if you vaccinate otherwise than by separate punctures, take care to produce local effects equal to those just mentioned. 3. Direct care to be taken for keeping the vesicles uninjured during their progress, and for avoiding afterwards the premature removal of the crusts. 4. Enter all cases in your register on the day when you vaccinate them, and with all particulars required in the register up to column 9 inclusive. Enter the results on the day of inspection. Never enter any results which have not been inspected by yourself or your legally qualified deputy. In cases of primary vaccination, register as "successful" only those cases in which the normal vaccine vesicle has been produced; in cases of re-vaccination, register as "successful" only those cases in which either vesicles, normal or modified, or papules surrounded by areolae, have resulted. When the vaccination of an unsuccessful case is repeated, it should be entered as a fresh case in the register. 5. Endeavour to maintain in your district such a succession of cases as will enable you uniformly to vaccinate with liquid lymph directly from arm to arm; and do not under ordinary circumstances, adopt any other method of vaccinating. To provide against emergencies, always have in reserve some stored lymph—either *dry*, as on thickly-charged ivory points, constantly well protected from damp; or *liquid*, according to the method of Dr. Husband, of Edinburgh, in fine, short,

uniformly capillary (not bulbed) tubes, hermetically sealed at both extremities. Lymph, successfully preserved by either of these methods, may be used without definite restriction as to time; but with all stored lymph caution is necessary, lest in time it have become inert, or otherwise unfit for use. If, in order to vaccinate with recent liquid lymph, you convey it from case to case otherwise than in hermetically sealed capillary tubes, do not ever let more than eight hours intervene before it is used. 6. Consider yourself strictly responsible for the quality of whatever lymph you use or furnish for vaccination. Never either use or furnish lymph which has in it any, even the slightest, admixture of blood. In storing lymph, be careful to keep separate the charges obtained from different subjects, and to affix to each set of charges the name, or the number in your register, of the subject from whom the lymph was derived. Keep such note of all supplies of lymph which you use or furnish as will always enable you, in any case of complaint, to identify the origin of the lymph. 7. Never take lymph from cases of re-vaccination. Take lymph only from subjects who are in good health, and, as far as you can ascertain, of healthy parentage; preferring children whose families are known to you, and who have elder brothers or sisters of undoubted healthiness. Always carefully examine the subject as to any existing skin disease, and especially as to any signs of hereditary syphilis. Take lymph only from well-characterised, uninjured vesicles. Take it (as may be done in all regular cases on the day week after vaccination) at the stage when the vesicles are fully formed and plump, but when there is no perceptible commencement of areola. Open the vesicles with scrupulous care to avoid drawing blood. Take no lymph which, as it issues from the vesicle, is not perfectly clear and transparent, or is at all thin and watery. From such a vesicle as vaccination by puncture commonly produces, do not, under ordinary circumstances, take more lymph than will suffice for the immediate vaccination of five subjects, or for the charging of seven ivory points, or for the filling of three capillary tubes; and from larger or smaller vesicles take only in like proportion to their size. Never squeeze or drain any vesicle. Be careful never to transfer blood from the subject you vaccinate to the subject from whom you take lymph. 8. Scrupulously observe in your inspections every sign which tests the efficiency and purity of your lymph. Note any case wherein the vaccine vesicle is unduly hastened or otherwise irregular in its development, or wherein any undue local irritation arises; and if similar results ensue in other cases vaccinated with the same lymph, desist at once from employing it. Consider that your lymph ought to be changed if your cases, at the usual time of inspection on the day week after vaccination, have not, as a rule, their vesicles entirely free from areole. 9. Keep in good condition the lancets or other instruments which you use for vaccinating, and do not use them for other surgical operations. When you vaccinate have water and a napkin at your side, with which invariably to cleanse your instrument after one operation before proceeding to another.

N.B.—Supplies of lymph are furnished to medical practitioners on personal application at 3 Parliament street, London, S.W., between the hours of 12 and 2; or by letter (unstamped) addressed to the Medical Officer of the Privy Council, 3 Parliament street, London, S.W.

**Poisonous Silk Gloves and Socks.**—Dr. Thompson Dickson writing to a daily contemporary says:—"On Saturday, a patient called upon me and exhibited her hands covered with very irritable blebs or blisters, and, after minute examination and questioning for the cause, she told me that during the week she purchased in Marylebone a new pair of silk gloves for two shillings; had worn them during a journey to Manchester and back, and that her hands had borne these vesications ever since. She wore the left glove more constantly than the right, and the left hand was consequently more affected than the right. I desired her to bring the gloves to me, and I found that they were of good quality spun silk, dyed of a light brown colour—the dye apparently being an aniline dye of coal tar origin. Spun silk takes the bright colour made from aniline very well, but the use of articles so dyed is dangerous. In the Museum of the College of Surgeons are preserved some brightly-dyed children's socks, which gave rise to a similar affection on the feet of a child (I believe in France). I also believe that the late Marquis of Hastings was once similarly affected." About eight years ago, when a rumour to a similar effect was spread about, we were requested by the Prussian Government to submit our dyes to the sworn chemist of the

government, Dr. Ziureck. After a minute inspection, in which several eminent professors of the Berlin University took part, Dr. Ziureck came to the conclusion, and reported to the government, that the aniline dyes we manufactured were absolutely harmless, or contained such trifling portions of injurious matter that any danger was entirely out of the question. We think it would be in the interest of this now very considerable trade if the English Government would follow the course the Prussian Government too about eight years ago.—LEVENSTEIN AND SONS.

**Malvern College.**—Tuesday week, the 1st instant, was "Speech Day" at this flourishing Institution, and the proceedings went off with the usual éclat. There was a very large and fashionable attendance, comprising many of the local families of distinction, and a large gathering of the parents and friends of the pupils. The Head Master, the Rev. Arthur Faber, presided. The prizes were distributed to the successful students by the Bishop of Worcester, and, with the grand old song of Dulce Domum, the proceedings terminated.

**British Medical Association: Annual Meeting.**—The Thirty-ninth Annual Meeting of the British Medical Association is now being held in Plymouth. This evening, Wednesday, the Address in Medicine by Dr. George Johnson; to be given to-morrow, the Address in Surgery, by Professor Lister, F.R.S.

**Whitehall, August 2.**—The Queen has been pleased to direct Letters Patent to be passed under the Great Seal granting the dignity of a Baronet of the United Kingdom of Great Britain and Ireland unto James Paget, of Harewood place, in the Parish of St. George, Hanover square, in the county of Middlesex, Esq., Serjeant-Surgeon Extraordinary to her Majesty, and the heirs male of his body lawfully begotten.—*Gazette*.

#### NOTICES TO CORRESPONDENTS.

**TO OUR SUBSCRIBERS.**—Gentlemen who have not paid their subscription for last year are respectfully reminded of the omission. The Publishers would also be much pleased to receive arrears of subscriptions due for several years previously, which, in too many instances, remain unpaid, notwithstanding frequent applications for settlement.

**NOTICE.**—Subscribers are respectfully reminded that payment by P.O.O., or crossed cheque, is the most convenient and safest mode of remittance. Stamps are unfortunately too easily disposable by dishonest persons.

All valid receipts are given upon printed forms. Subscribers and advertisers are particularly cautioned against making any payments without the production of such a receipt. Cheques or P.O.O. should be made payable in England, to A. A. Tindall; in Ireland, to A. H. Jacob, M.D.; in Scotland, to MacLachlan and Stewart.

MR. J. PARKINSON.—Forwarded.

M.R.C.S.—You will find your name in the Pass Lists published in our last number.

STUDENT.—On September the 14th.

DR. GAVIN, Broadway, Boston.—Note and cheque received paying your Subscription to 31st December, 1871. Receipt not sent to save foreign postage. The review of the "Boston Hospital Reports" is in printer's hands. Thanks for other transmissions to us. If you can send us dates of numbers wanted to complete your sets, we will probably be able to forward them.

#### A LIFE ASSURANCE SOCIETY.

A Physician forwards to us the particulars of a most objectionable mode a certain not very respectable Life Office pursues to induce people to secure their lives, for the accuracy of which he can vouch. The system pursued is, in his own language, briefly this. A *disinterested gentleman* calls once or twice and buys some small article; enters familiarly into conversation, and tells the tradesman he works too hard, and by gentle reminders as to the inevitable consequence of overwork, persuades him to insure his life in a certain office, named by this *disinterested gentleman*. In a short time, the amiable secretary of this Society arrives,—all business, of course,—suddenly appears a young Medical man, defined as a keen Scotchman, who examines the tradesman, particularly his heart. Observe the caution, as told me by my patient: "I fear your life is not a safe assurance for ordinary terms. The veins of the heart are diseased." Of course this awful statement frightened the poor fellow; he becomes more anxious than ever to secure his life. The game is well watched. The amiable secretary calls again, armed with the first examination of the doctor, and says "for £... so much to pay at once on the policy. The tradesman gets rather vexed over all this, and, suspecting trickery, tells this individual he will have nothing to do with them, and he cannot pay the money required. As a last resource, the amiable secretary, seeing the victim is likely to be lost to them, says, "Oh, my dear Sir, don't inconvenience

### CLINICAL LECTURES ON THE DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE VIII.

*Fibrous tumours—Definition of—Varieties of—Sub-peritoneal—Sub-mucous—Intra-mural—Enucleation—Intra-uterine injections—Influence of pregnancy on—Spontaneous cures.*

I SHALL proceed to-day, gentlemen, to direct your attention to the subject of fibrous tumours of the uterus, a subject of quite as great importance as that of polypus which was last under our consideration, though unfortunately more often beyond the reach of surgical interference.

A fibrous tumour may be defined as a growth composed of fibrous tissue identical in structure with that of the uterine wall, but "disconnected" from it, being in general surrounded by a capsule of dense fibro-cellular tissue which "is peculiarly dry and loose, so that when one cuts on the tumour it almost of itself escapes from its cavity." (Paget, "Surgical Pathology," p. 474), This fact of the fibrous tumour of the uterus being by means of its capsule disconnected from the surrounding tissue distinguishes it from the ordinary fibrous polypus, a distinction which cannot often be made during life. The annexed diagrams (Plate V.) copied from Paget illustrate the difference between these two growths, the one (a) being a section of an uterine out-growth or polypus, the other (b) of a uterine fibrous tumour, the former being

"continuous," but the latter "discontinuous," with the substance of the uterus although both in outward appearance are very similar

It would be quite impossible in the brief limits of a clinical lecture to enter at any length into the pathology of a subject so extensive as that of fibrous tumours of the uterus. I can only glance at a few of the leading characteristics, referring such of you as desire further information on this interesting subject to the works of Paget, West, McClinton, Matthews Duncan, and others. Fibrous tumours are met with of all sizes from that of a grain of shot upwards; those of large size being by no means of infrequent occurrence, while cases are on record in which they have attained a size greater than that of the uterus at the full term of pregnancy and a weight of 70 lbs. or even more. Again they may be solitary but usually two or more are present in the same patient; they may spring from the peritoneal surface of the uterus and can be felt through the abdominal wall. They may grow from the submucous tissue of the uterus or finally be developed within the walls of the organ; consequently fibrous tumours are spoken of as belonging to one of three classes—namely sub-peritoneal, sub-mucous, and intra-mural, according as they are found to grow in one or other of the situations I have designated. Of these the extra-uterine or sub-peritoneal being entirely beyond the reach of treatment must be dismissed after a brief notice. They vary in size and appearance in even a greater degree than either of the other varieties, sometimes being numerous, small in size, and sessile, giving the surface of the uterus a nodulated appearance or on the other hand attached by a pedicle which is sometimes short and thick as shown in Plate VI, or at other times so long and slender as to permit the tumour to float as it were free in the abdominal cavity, and finally even to dis sever itself from all connection with the womb, and possibly to become attached to some other portion of the peritoneal surface. When sub-peritoneal fibroids are pedunculated they sometimes descend into the pelvis, and then by their pressure on the neighbouring organs give rise to most distressing symptoms. When this occurs the patient's sufferings are sometimes very severe, incessant

desire to micturate or total inability to pass water being frequently experienced. Of course it is impossible to give relief unless the tumour be raised from its position and replaced above the brim. This is always a matter of great difficulty, sometimes an impossibility. The tumour invariably lies in the posterior *cul de sac* between the rectum and uterus occupying much the same position which the impregnated uterus does when retroverted. With the view of raising it above the brim Dr. Kidd has adapted to this case the method suggested by the late Dr. Halpin, of Cavan, for restoring the uterus when retroverted during pregnancy to its normal position. He introduces one of Barnes's largest sized India rubber bags into the rectum and gradually distends it with water by means of a syringe, while at the same time steady pressure is made with the finger on the tumour through the vaginal wall. In this way you will often succeed in raising the tumour and making it slip up into the false pelvis. Unless indeed the case be of long standing, and it be bound down by adhesions, should these exist your efforts will be not only useless but injurious.

Sub-peritoneal fibrous tumours do not necessarily give origin to menorrhagia, indeed as a rule they do not seem to influence menstruation at all. Thus in the case delineated in Plate VI. the catamenia were quite regular. These tumours also generally spring from the posterior surface of the uterus; this however is far from being always so, thus in the patient from whom the drawing (Plate VI.) was made the tumour grew from the anterior wall. This case was interesting too as affording an example of that form of the disease termed *fibro-cystic* in which a cyst is developed within the structure of the solid tumour. The patient was under the care of my friend Mr. Morgan, in Mercer's Hospital, through whose kindness I had an opportunity of seeing her. She appeared to be about thirty-five years of age, was married, but had never been pregnant. She stated that two years ago she detected a small, hard, moveable tumour in the left iliac region, that a year subsequently she perceived what she supposed to be another distinct tumour in the right side; they were however but projecting portions of one large central growth which steadily increased till she had attained the size of a woman when near the full term of pregnancy, but she did not think that for the last few months she had become larger. Menstruation appeared regularly at intervals of three weeks, fluctuation was everywhere very distinct, and there was universal dulness on percussion. On making a vaginal examination the tumour could be easily felt blocking up the brim of the pelvis. The anterior lip of the os uteri which was greatly hypertrophied projected into the vagina, the uterus lay quite behind the tumour, the diagnosis of uterine cystic disease was made, and all idea of surgical interference was given up. This patient subsequently died of an attack of acute peritonitis and we had an opportunity of verifying our diagnosis. The tumour which was of enormous size consisted mainly of an immense cyst; it sprang from the anterior and upper surface of the uterus, being connected to it by a short thick pedicle. The drawing which accurately represents both the size, shape, and position of the tumour was made by my friend and former pupil Dr. Hamilton Moorhead.

The sub-mucous pedunculated fibrous tumour is prior to its removal, in no way distinguishable from, and is to be treated in a manner identical with the ordinary fibrous polypus of which I have already spoken, I shall not therefore allude to it any further but shall proceed to the consideration of the third and most important variety of these tumours.

Intra-mural or as they are sometimes termed the parietal or interstitial fibrous tumours are of frequent occurrence. They differ from the sub-peritoneal in two important features—namely, that they nearly always cause menorrhagia and that they nearly as invariably stimulate the uterus to enlarge an effect not often produced by the other form. Thus in Dr. Morgan's case just alluded to,

though the tumour weighed upwards of 11 lbs. and was at least 25 inches in circumference, the uterus was of nearly its normal size and shape, while the presence of even a very small intra-mural tumour has been known so to stimulate the womb that it has grown to a length of five or six inches while its walls have attained a thickness of an inch or more. Dr. West in his work "On Diseases of Women" mentions a case illustrating this fact. The growth of an intra-mural fibrous tumour is sometimes very slow. In a case at present under my observation and in which the womb has attained a length of five inches no appreciable change has taken place during a period of two years. On the other hand the tumour sometimes steadily increases in size and then one of three results must occur—either it will bulge out the peritoneal surface of the uterus and possibly may become a sub-peritoneal tumour, or it may continue to grow in the substance of the uterus, the whole of the organ enlarging as the tumour increases, or it may project into the uterine cavity carrying before it a covering of the muscular tissue of that organ. It is easy to conceive how this process if continued may result in the formation of an intra-uterine tumour, connected with the wall by a pedicle consisting of muscular tissue continuous with that of the uterus and of the mucous membrane covering it, that this pedicle may in time elongate, and as it lengthens become more slender, till finally it passes out of the uterus or even spontaneously breaking its attachment is expelled from the vagina, nearly all writers with the exception of Dr. Matthews Duncan admit the possibility of this process. He however thinks that the uterine wall never elongates before the true intra-mural tumour, but that the tumour is expelled *bare* into the uterine cavity, enucleation of the tumour, a process to which I shall have to refer by and by, having taken place spontaneously. However one thing is quite certain that these growths frequently present themselves as well-defined tumours projecting into the cavity of the uterus.

Here is a specimen of a tumour so circumstanced, you see that it is connected to the uterine wall by a very extensive attachment the circumference of the base being greater than that of any other portion of the tumour. It was taken from the body of a patient who recently died in hospital. She was a married woman, aged fifty-three. About five years ago she ceased to menstruate, but after a considerable interval observed a sanguineous discharge again to appear. This at first recurred with tolerable regularity, but gradually became more and more profuse till finally it was continuous. Some months ago she perceived a tumour to exist in the abdomen which at one point on the left side was extremely tender to the touch; she also experienced constant pain in, and was unable to lie on that side. When admitted into hospital she was in a very anæmic condition.

On passing the hand over the abdomen a large tumour could be felt lying rather to the left side which at one point was very tender to the touch. On making a vaginal examination this tumour proved to be the uterus greatly enlarged. The sound passed to the depth of five inches. I at once proceeded to dilate the cervix with sea-tangle on the removal of which this large tumour was detected projecting into and filling up the whole cavity of the uterus. The patient's condition rendered it absolutely necessary that its removal should be immediately attempted. I endeavoured to accomplish this with Marion Sims' intra-uterine *écraseur*, but as stated in a former lecture I found that instrument quite unsuitable for the purpose. I then tried an ordinary wire *écraseur* and succeeded in carrying a wire round the tumour, but the wire (an iron one) broke. Three times I succeeded in encircling the tumour with the wire but the strain to which it was subjected was too great and on each occasion it broke. As the patient was now much exhausted I desisted from any further attempt; besides I hoped that the great pressure to which it had been subjected might have been sufficient to destroy the vitality of the tumour, and that it would slough off. Matters went on very well for three days,

indeed on the third day she expressed herself as being quite well. There was not any hæmorrhage; she had no pain on pressure, and the pulse was quiet; but on the night of the fourth day she was suddenly seized with a violent rigor, complained of intense pain over the abdomen, sunk into a state of low muttering delirium, and finally died comatose. On opening the abdomen after death hardly any trace of peritoneal inflammation presented itself, but on raising the omentum that point on the fundus of the uterus which as previously noticed had been so excessively tender to the touch, was found to be in a condition of actual mortification. On opening the uterus this enormous tumour was seen; it was nearly five inches in length and its base where the ligature had surrounded it measured nine inches in circumference. I look back on this case with much regret; had I been acquainted at the time with the value of the steel wire I believe I should have succeeded in removing this tumour large as it is and probably have saved the woman's life.

Very frequently however fibrous tumours appear as mere protuberances bulging out the uterine wall as is shown in Plate V. Such tumours as these can hardly be removed with an *écraseur*, and yet you cannot leave them alone for health is undermined and life itself frequently endangered by the hæmorrhage arising from their presence. The treatment to be adopted in such cases necessarily divides itself into the palliative and the radical; the former consists of restraining the profuse flow which occurs at each menstrual period by plugging the vagina as recommended in a former lecture, and by the administration of hæmostatics such as gallic acid, alum, &c., while ergot alone or combination with the perchloride of iron is often useful. But this plan of treatment is most irksome to the patient, and can only be looked on as a means of delaying the fatal results which ere long must follow if more energetic means be not adopted.

Medicines without number have been administered with the view of causing the absorption of fibrous tumours of the womb. Prominent among these are the bromides. I have tried them fully and freely, and believe them to be of very little, if any, use. It would be waste of time for me to go through the long list of drugs which have been recommended in these cases. I do not wish to deter you from trying them in your future practice; they will probably do no harm, but I think I can promise that they will effect little good. For myself I have lost all faith in the resolvent powers of medicines of this class in the disease at present under consideration.

The very limited good produced by medicines has induced obstetric surgeons to adopt energetic treatment, no less than five methods having been recommended and practised with the view to the radical cure of these embedded fibrous tumours. They are—1st, incising the cervix uteri; 2nd, incising the tumour; 3rd, cutting into the tumour and destroying a portion of its tissue, a process to which the term gouging has been applied; 4th, enucleation of the tumour; 5th, avulsion or the forcible tearing away of the tumour from its attachment. Incising the os was first practised in this city by Dr. McClintock.\* This operation has been founded on the theory which, according to Mr. Baker Brown, is "that the division of the os and cervix uteri permits the fibres of the body of the uterus to contract upon the contained tumour, and thereby to compress the vessels and prevent hæmorrhage." Whether this be the true explanation or not, one thing is quite certain that the operation is often followed by good results, and in the case of very large tumours which are contained within the uterus and when the cervix is thinned and spread over them the operation is fully justified—the incising of the tumour has been practised by Dr. Atlee in America, by Dr. Tracy of Melbourne, and others, with success, a success which is probably due to the fact that the vitality of these tumours is nearly if not altogether destroyed by the incisions having divided their capsules, for the fibrous growth itself

is endowed with but a very low degree of vitality. I have not met with a suitable case in which to try this treatment, but I certainly should not hesitate to do so were dangerous hæmorrhages to occur in a patient in whom an intra-mural tumour existed, which I could not control by other means.

Enucleation, that is the cutting down on and dividing the capsule, and then grasping the tumour and turning it out of its capsule, is an operation suggested by a consideration of one of the processes by which Nature occasionally effects a spontaneous cure, in which the capsule and investing covering of the tumour becoming thinned at one point, either by a process of absorption or ulceration, the contained tumour is then pushed out by the contractile power of the uterus and is finally expelled. Enucleation is advocated by Dr. Matthews Duncan with his usual ability. He also practises with great success, the operation of avulsion, that is the seizing of the tumour with a strong vulsellum and forcibly dragging it from its attachments.

Avulsion is practised by Dr. Duncan in cases in which spontaneous enucleation has been already partially begun, or where that stage having been artificially commenced has proceeded to a certain extent. He considers it to be the proper practice in those cases of fibrous tumours in which the patient's life is in great danger which medical treatment is unable to avert. I am not able to speak from personal experience as to the value of the operation, but you will find full details of Dr. Duncan's views on the subject in the twelfth volume of the *Edinburgh Medical Journal*. I am equally without experience as to the merits or demerits of "gouging," but am of opinion that surgical means have been carried rather too far in the treatment of some of these fibrous tumours.

There is a less heroic mode of treatment I would have you bear in mind, and under certain circumstances to practise before having recourse to surgical measures. It is the injection after previous dilatation of tincture of iodine or of the liquor of the perchloride of iron into the uterine cavity. This practice is warmly advocated by Dr. Routh, of London, and if the cervix and os internum be first dilated so that the injection may have a free and rapid exit, I do not think that it is likely to be followed by unpleasant symptoms. My friend, Dr. McClintock, informs me that he has recently injected tincture of iodine with marked success in the case of a lady whom I had an opportunity of seeing with him, and in whom alarmingly profuse menstruation occurred from time to time, and which he ascertained to be dependent on the presence of a large fibroid.

Dr. Matthews Duncan has recorded two cases in which he successfully restrained dangerous hæmorrhage depending on the existence of a tumour in the uterus by the injection of the liquor ferri perchloridi, one drachm of the fluid being in each case injected by means of a hollow sound into the cavity of the womb. In his cases the cervix does not seem to have been dilated, a precaution I should always adopt.

I have now given you an outline of the pathology and treatment of the various forms of fibrous tumours, but there yet remain two interesting and important phases of their history, to which I must allude to before concluding the subject, the one, the increase and subsequent decrease in their size, which is sometimes observed, the other their occasional absorption, transformation, or even elimination.

All fibrous tumours, especially the sub-mucous, when they hang into the cavity of the uterus are liable to become edematous, and to this cause many of the recorded cases of enlargement and subsequent decrease in their size is referable. But in addition to this cause, menstruation and pregnancy undoubtedly influence both the condition and size of these growths. In many cases a fibrous tumour what ordinarily is productive of no discomfort to the patient becomes at each menstrual period the seat of pain. This is a fact I have several times noticed. That actual increase in bulk should also occur at the epoch is easily understood. The following case illustrating the fact is

\* "Diseases of Women," p. 149.

recorded by Dr. Ernest Lambert of Paris:—"Age of patient, thirty-eight. For ten years past a tumour appeared before each menstrual epoch, disappearing in turn to reappear again; for a year it has ceased to disappear, and has become the seat of severe pain." After death a large fibrous tumour was found growing from the anterior surface of the uterus. From the same author I quote the two following instructive cases:—"The first on the authority of M. Depaul, who relates that having been summoned to a patient at a distance from Paris he found three physicians in attendance on a primipara, supposed to be three months pregnant. She had suffered for some time past great difficulty both in passing water and in defecation, and for four days previous to M. Depaul seeing her had been unable to empty either the bladder or rectum, even the catheter could not be passed except with great difficulty. She suffered from the most powerful expulsive pains and her agony was very great. M. Depaul recognised the existence of a large fibrous tumour which filled the pelvis; the patient's state was one of great danger. With difficulty he reached the os uteri, introduced a sound and brought on premature labour. The next day a fœtus flattened like a sheet of cardboard was expelled; in a short time this tumour had decreased to a third of its former size, and at the end of four months was not larger than a small apple; it was situated in the anterior wall of the uterus near the neck.

X—, a woman, æt. forty-four, who had given birth to several children, was admitted into hospital on the 21st of March, 1869. The membranes had ruptured before her admission, and the feet of the child were in the vagina. The child was extracted alive, and in a few minutes the placenta was expelled. On placing the hand on the abdomen shortly after, a tumour as large as a child's head was felt at the fundus of the uterus; supposing that it was a case of twins a vaginal examination was made, but no fœtus could be felt. As the placenta had come away and as there was not any hæmorrhage it was not deemed right to explore the interior of the uterus, but the hand laid on the abdomen easily detected the presence of a tumour as large as the head of a fœtus at the eighth month of pregnancy; below this large tumour a smaller one could be felt, which was supposed at first to be the elbow of the child; careful auscultation however failed to detect the sounds of the foetal heart; the diagnosis seemed very obscure. The woman however declared that there was no cause for anxiety as she had these tumours after each confinement, and that they always disappeared in a short time. The next day the large tumour was unchanged, but in place of the sharp projecting tumour a globular one of smaller size existed; two days later the large one only could be felt. She died of fever on the 12th of April, twenty-three days after delivery. On making a *post-mortem* examination two fibrous tumours were discovered, the larger the size of a hazel nut, the other still smaller. Dr. Lambert concludes by saying, "we saw in this case a woman in whom at the moment of her accouchment there existed in the parietes of the uterus tumours of which one had the volume of the head of a fœtus at the eighth month; these tumours could be as clearly made out as if they had been laid bare, for the abdominal walls were very thin and flaccid, and the autopsy discovered but two little fibrous tumours, of which the largest was but the size of a nut."\* It would be quite foreign to the scope of these lectures for me to enter on the subject of the influence which fibrous tumours exercise on pregnancy, but the two cases just quoted clearly prove that pregnancy stimulates them to a very dangerous degree, and this knowledge should certainly induce us to warn any woman in whom they exist should she consult us on the subject, that marriage should not be thought of.

Fibrous tumours when left to themselves not unfrequently undergo changes which may not only alter their character but also result in an actual cure. One of the

most remarkable of these changes is the developement of cavities or cysts in their substance. These are specially likely to form in tumours the texture of which is loose. According to Mr. Paget this may be due either to a local softening and liquefaction of part of the tumour, with effusion of fluid in the part affected, in which case the cavities are irregular and without distinct parietes, or they may be true cysts, their cavity being lined by a membrane; in either case they may be small and numerous, or of such great magnitude as to be mistaken for and treated as ovarian cysts, a very serious mistake indeed, and one unfortunately too often made. I shall however have more to say with reference to this point when I come to speak of ovarian tumours, and shall therefore for the present defer making any further remark on this part of the subject.

But Nature also makes an effort and not unfrequently a successful one to effect a cure in these cases. Dr. McClintock has pointed out five methods by which this result may be attained, namely, by, 1st, absorption—2nd, detachment—3rd, calcareous transformation—4th, sloughing or disintegration—5th, expulsions by the uterine contractions. Examples of absorption have been frequently recorded and are sufficiently numerous to induce us to postpone surgical interference if the patient be near the climacteric period of life and the symptoms from which she suffer be not urgent. I have two such cases at present under observation. In one menstruation which for several years past has been very profuse is now at the age of forty-nine becoming much more moderate in quantity; this patient refused to submit to any local treatment—Detachment and separation is only likely to occur in cases of the sub-mucous variety, for in the intra-mural the formation of a long pedicle is very unlikely, and according to Dr. Matthew Duncan never does take place, and unless this happens the spontaneous detachment is a very unlikely occurrence.

But on the other hand in the case of the embedded intra-mural tumour a cure sometimes takes place by a process of sloughing which either gradually breaks up the growth, or if that process be confined to its muscular and mucous coats, frees the tumour and permits it spontaneous enucleation.

Again cases are met with in which calcareous deposits have been formed in the substance of fibrous tumours, and it is possible that the process may extend to the entire tumour, although I am not aware of any case being recorded in which this took place—Expulsion is but a variety of the curative process first spoken of, the uterus nearly always makes an attempt to expel any substance which is formed within its cavity, consequently polypi and fibrous tumours are as a matter of fact frequently extruded by its contractions; but in the case of the latter the expulsion seems to be of but doubtful occurrence unless as the final stage of the process of spontaneous enucleation just spoken of.

I have purposely avoided at present entering into the question of the differential diagnoses of fibrous tumours because I think I shall treat this part of the subject with greater advantage when considering that of ovarian disease with which alone it is likely to be confounded, for to mistake a fibrous tumour for pregnancy is hardly possible; the size and shape may indeed resemble that of the pregnant uterus, but the slow increase in its size and the occurrence of menorrhagia should alone in most cases suffice to prevent error. There is one symptom indeed often present in a fibrous tumor which may mislead the careless observer, and that is the occurrence of a *bruit de soufflet* which may possibly be confounded with the placental murmur; this is always synchronous with the pulse and can generally be increased by pressure. It is of but little value as a diagnostic sign and I merely mention it to put you on your guard lest you should be misled by its occurrence to suppose pregnancy existed. You must not however forget that pregnancy is not incompatible with the presence of a fibrous tumour, and a very serious complication it is.

## ADVANCEMENT OF SCIENCE.

## FORTY-FIRST MEETING, HELD AT EDINBURGH.

LAST week we gave abstracts of several of the addresses. We now offer a selection from the proceedings of the Sections. In consequence of the great length of the proceedings we do not attempt a full report, but only notice those papers most closely connected with our professional pursuits.

Sir DUNCAN GIBB read a paper on "The Uses of the Uvula." He commenced by saying that the true functional uses of the uvula had never been wholly understood, and then entered into a description of its composition, situation, and relation to neighbouring muscles. Anatomists describe the action of the uvular muscle as an elevator, and therefore shortens the uvula. It is, however, a sentinel to the fauces, especially in the act of deglutition, for when any substance comes in contact with it, it excites the action of all the neighbouring muscles until it is got rid of. But it possesses a function of not less importance in holding the soft palate tense and firm in the medial line against the wall of the pharynx during the act of deglutition itself, and thus prevents the passage upwards of fluid or solid substances behind the nose. This was supported by experiments upon a person who had lost the bones of the nose, permitting of a view of the action of the soft palate from its nasal aspect during deglutition, with or without food. Under either circumstance, a double arch was seen in the form of two convex swellings, held in a state of firm tension by the action of the uvula pressing down the centre of the soft palate, with its end resting flat against the wall of the pharynx. There was the *motor uvula* muscle situated superficially, like a distinct band, tied round the soft palate in its most important resisting part, to prevent the possibility of food passing upwards, and in this it was supported co-ordinately by all the neighbouring muscles concerned in the act of deglutition. There also was a fact not previously known—viz., the action of the uvula as a *point d'appui* in holding the soft palate tense in the middle line against deglutition, at the same time that the muscle acted as a compressor of the soft palate itself. Its tension ceased the moment that the constrictors of the pharynx had fully exerted their influence over the substances swallowed. Whilst the uvula has its special uses in the act of deglutition, it exerts a not less decisive influence upon the voice when uttered in a very loud tone, or in singing the higher registers, in both sexes; then its character as a levator or shortener is exerted. If this power is impaired by removal of the muscular (not the membranous) end, then the singing powers are damaged. The author now described the appearance and action of the uvula as seen in singing the higher notes, its point becoming almost invisible, and the soft palate being drawn backwards and upwards, diminishing the space between it and the wall of the pharynx. The movements of the uvula are exceedingly rapid, and vary with the continuous or quavering character of the singing notes. In the shakes of the voice it is seen to be undergoing a series of short ups and downs, at every inspiration descending, and then rapidly ascending, and keeping up until the note, prolonged or otherwise, is finished. Some remarks were made upon elongation of the uvula and its effects, a distinction being made between its elongated membranous end and the true muscular tip which should not be meddled with. Speech, the author said, was modulated by the soft palate and uvula, and the motor power of the latter is unquestionably exerted in pronouncing the letters K, Q, and X, with their associations, more especially the gutturals of the various languages. He summed up the uses of the uvula as follows:—"1. It acts as a sentinel to the fauces in exciting the act of deglutition when anything has to be swallowed. 2. It compresses the soft palate and holds its posterior free border firmly against the wall of the pharynx in deglutition so that nothing can pass upwards. 3. It modifies speech in the production of loud declamation and the guttural forms of language by lessening the pharyngo-nasal passage when it acts as an elevator. 4. Its elevating power is increased to the most extreme degree in the highest ranges of the singing voice, and is very moderately exerted in

the lower ranges. 5. Therefore, in its uses, deglutition and vocalisation are the functions that are intimately associated with the uvula, and both become impaired more or less if it is destroyed, wholly removed, or seriously injured."

Sir DUNCAN GIBB read a paper on "Abnormalities of the Larynx," in which he described a rare instance of absence of both arytenoid cartilages in a girl of eighteen. Likewise one in which the epiglottis possessed the shape of a trefoil leaf, and two others in bags of fissure of the same cartilage.

## REPORT ON GERM AND PROTOPLASMIC LIFE.

DR. F. GRACE-CALVERT, F.R.S., Manchester, read papers on these subjects, of which the following are abstracts:—

*Germ Life.*—The question of building ovens for disinfecting purposes gives the subject of this paper more than a merely scientific interest, as it thus becomes one of practical importance. As it is found that certain forms of life can exist when exposed to a temperature nearly equal to that at which the charring of organic matter commences, it is unsafe to assume that the particular forms of life which propagate certain forms of disease will be destroyed below this temperature. As from the nature of the case it can only be partially applicable, and it is at present not proved effective where it is applicable, it is unadvisable to spend public money until a greater degree of certainty is arrived at. The experiments described were not, however, undertaken with an intention of influencing the settlement of this question, but were part of a series on the question of putrefaction and the development of life. It has hitherto been assumed by the advocates of the theory of spontaneous generation that of 212 deg. Fahr., or the boiling point of the fluid operated on, was sufficient to destroy all protoplasmic life, and that any life subsequently observed in such fluids must have been developed from non-living matter. To determine this point, experiments were made with solution of sugar, hay infusion, solution of gelatine, and water that had been in contact with putrid meat. To carry out these experiments I prepared a series of small tubes made of very thick, well-annealed glass, each tube about four centimetres in length, and having a bore of five millimetres. The fluid to be operated upon was introduced into them and left exposed to the atmosphere for a sufficient length of time for germ life to be largely developed. Each tube was then hermetically sealed and wrapped in wire gauze. They were then placed in an oil bath, and gradually heated to the required temperature, at which they were maintained for half an hour. The sugar solution was prepared by dissolving one part of sugar in ten parts of common water, and then exposed to the atmosphere all night, so that life might impregnate it, then placed in tubes, and allowed to stand five days. Some of the tubes were kept without being heated, others heated to 200, 300, 400, and 500 deg. Fahr. respectively. After being kept twenty-four days, the contents of the tubes were microscopically examined. In the solution not heated much life was seen; at 211 deg. the sugar was slightly charred but the life not entirely destroyed, while at 400 and 500 the sugar was almost entirely charred and no trace of life observed. A small black vibrio observed resists the high temperature and all chemical solutions. The hay infusion was made by macerating hay in common water for one hour, filtering the liquor, and leaving it exposed to the atmosphere all night, when it was sealed in the small tubes. The results were examined twenty-four days after being heated. In this case, as in the sugar solution, life was observed in the solutions heated to 200 and 300 deg. Fahr., while in those heated to 400 and 500 deg. Fahr., life was destroyed. In the solution not heated, fungus matter was observed, while none appeared in any of the heated solutions. A solution of gelatine of such strength that it remained liquid in cooling was exposed to the atmosphere for twenty-four hours, and introduced into the small tubes which were sealed and heated. The fluids were examined twenty-four days after being heated. The animalcules in this case were principally of a different class to those observed in the two preceding cases, and this class were injured at 100 deg. F. At 212 a considerable diminution in the amount had taken place, whilst at 300 deg. all life was destroyed. Water was placed in an open vessel, and a piece of meat suspended in it until it became putrid. This fluid was placed in the usual tubes heated, and the contents examined after twenty-four days. In this case life was still observed at 300 deg. F., while at 400 deg. it had disappeared. As previous experimenters have not exposed their solutions to so high a temperature as 300 deg. F., the life which they

found was due to the development of germs remaining in the fluid. Parts of the putrid meat solutions that had been heated were mixed with albumen, to ascertain whether they still possessed the power of propagating life, the result being that up to 300 deg. F. life and its germs had not been destroyed, whilst at 400 deg. they had. Putrid meat liquor was exposed for twenty hours to a temperature ranging from the freezing point to 17 deg. below that point. Immediately after melting the ice the animalcules appeared languid, and their power of locomotion was greatly decreased, but in two hours they appeared as energetic as before.

#### SANITARY MEASURES FOR SCOTTISH VILLAGES.

Sir JAMES E. ALEXANDER, in the course of a paper on the above subject, pointed out instances of over-crowding, bad ventilation, and evil habits, which rendered the amenity of many Scotch villages so unfavourable. As to the remedies for the existing state of things he was of opinion that ministers of the gospel could exercise a wholesome influence in improving the habits of the people in their visits. Amongst other things, by promoting the practice of music they might lead the people to abandon the practice which was so demoralising both to body and soul—that of resorting to strong drink.

MR. WILKINSON, Hertfordshire, said that in a village he could name there were no less than fifty public-houses. Every one more than was needful was an additional temptation to the poor man to spend his money. If they could have a diminution of the beershops, the result would be the improvement of the sanitary, moral, physical, and, he would say, the religious aspects of the poor of our villages.

MR. LAMPOR was of opinion that not until they had the poor educated to understand that their pockets were concerned in living in more wholesome dwellings, would a reform in this respect be secured. It was true philanthropy to provide for the labouring man as good a dwelling as possible, but to charge him a fair market price. He was of opinion that their endeavours to procure better dwellings for the poor would be useless as long as in Edinburgh and everywhere else houses were not built with special reference to ventilation.

MR. HIRST said the supply of water was very bad in many of the villages of Scotland. He thought that if tanks were constructed a constant supply of water might be obtained for many of the small villages. A great deal of water, he thought, was now wasted in the drainage system which had come into vogue.

MR. WILLIAMS, Wishaw, related some experience he had had in the place where he resides in the provision of houses for workmen. He had been able to construct houses containing three rooms, and to let them at so low a rent as 3s. per week, which yielded him 5 per cent. on the capital expended. The house accommodation of the poor of a country was, in his opinion, closely connected with the morals of a country, and he was sure they would labour in vain to bring down the high percentage of illegitimacy so long as the habits of the poor rendered morality so improbable.

Rev. WM. CAINE, Manchester, said the deficiency in house accommodation led to a great deal of immorality, and produced a great deal of crime. He was also convinced that they could never remove these evils until they lessened the number of public houses.

Professor RAMSAY, Glasgow, alluding to the remarks made by Mr. Knox, said that in Glasgow a ticket was put up at every house in the poorer localities stating the number of cubic feet of air it contained, and the number of persons of respective ages it was allowed by the Police Act to accommodate.

MR. A. MACKNIGHT thought the great want of Scotland was some Act of Parliament which would compel the proprietors to give up land at a reasonable price wherever it was required for building houses for the poorer classes.

#### GEOLOGICAL SYSTEMS AND ENDEMIC DISEASES.

MR. T. MOFFAT, M.D., read a paper "On Geological Systems and Endemic Diseases." He said that in a paper which he read last year, he stated that the district in which he lived consisted geologically of the carboniferous and the new red or Cheshire sandstone systems; and that the inhabitants of the former were engaged in mining and agriculture, and those of the latter in agriculture chiefly. Anæmia with goitres was prevalent amongst those on the carboniferous system, while it was almost unknown among those of the Cheshire sandstone, and phthisis was also more prevalent among the

former than the latter. As anæmia was a state in which there was a deficiency of oxide of iron in the blood, he examined chemically the relative composition of wheat upon a soil of Cheshire sandstone, carboniferous limestone, millstone grit, and a transition soil between the Cheshire sandstone and the grit. The analysis showed that wheat grown upon Cheshire sandstone yielded the largest quantity of ash, and that it contained a much larger quantity of phosphoric acid and oxide of iron than that grown upon the other formations. The analysis also showed that the wheat grown upon the carboniferous system was deficient in phosphates or nutritive salts. With the view of ascertaining whether the bread of those who dwelt upon the two systems was relatively as deficient in the nutritive elements as the wheat, he collected twenty samples of bread used by twenty different families living on each system, and the analysis afforded results as conclusive as the examination of the wheat. The deficiency of the nutritive salts in the bread, compared with those in the wheat was remarkable, no doubt owing to the removal of the bran from the flour with which the bread was made. From statistics it was found that the number of deaths from anæmia was greater on the carboniferous than on the new red sandstone system at all elevations, and that there was a greater number of deaths from cancer on the red sandstone than on the carboniferous system. The number of deaths from struma diminished with the increase of elevation. On the carboniferous formation on both sides of the estuary of the Dee at a mean height of 30 feet, the number of deaths per 1,000 of population from struma was 14 and 22, greater than it was on the Cheshire sandstone of nearly the same elevation; while at a mean height of 500 feet it decreased to only three above it. This diminution with elevation in the death-rate of strumous persons he attributed to meteorological causes, the chief of which he believed to be atmospheric ozone. The practical deductions to be drawn from this enquiry were, that all young persons living on a carboniferous formation having symptoms of incipient goitre and anæmia ought to be moved to a soil upon red sandstone; that persons of strumous habit ought to reside upon sandstone of an elevation of at least 800 or 1,000 feet above the sea; and that both classes of persons should live upon food—both animal and farinaceous—which contains the maximum quantity of oxide of iron and the phosphates or nutritive salts. Medical men could not too much impress upon the minds of the public the importance of using flour made from the whole of the wheat or "whole grain."

MR. G. A. LEBOUR, H.M. Geological Survey, said that in a part of Northumberland, where the carboniferous district contained a thin bed of limestone, the inhabitants suffered very much from goitre.

Professor YOUNG said that those who undertook investigations of this kind should limit their examinations to one class of diseases, or a group of diseases sufficiently distant pathologically as not to interfere with one another.

Sir RICHARD GRIFFITH said that in Ireland they had plenty of carboniferous limestone, and not a case of goitre was known in those districts.

Professor HULL added his testimony to the healthful character of the new red sandstone of England as a foundation for houses and towns. He thought the towns of England should be built on the sandstone, and that the coal measures should be given up to the production of coal, oil, &c. In Birmingham, which had never been visited by cholera, the new red sandstone was peculiarly adapted to promote the health of the inhabitants. It was porous and dry, and the most wonderful natural filter which existed in these islands. However, the most healthful situations and formations might be converted into pestiferous dens by the neglect of ordinary sanitary arrangements, and he hoped that increased attention would be paid to those ordinary sanitary arrangements.

A MEMBER said he thought Dr. Moffat's deductions were mere coincidences, and that they were not traceable to the causes to which he referred. The character of the food was very fluctuating, depending as it did on the state of the markets and crops, and it was also a fact that the people were largely fed with food which was imported.

DR. MOFFAT, in his reply, said that goitre was found to decrease after the introduction of a different kind of food, and that sheep in that district were peculiarly liable to anæmia.

#### ON THE DICHOISM OF THE VAPOUR OF IODINE.

Professor ANDREWS read a paper "On the Dichroism of the Vapour of Iodine." The fine purple colour of the vapour of iodine arises from its transmitting freely the red and blue rays

of the spectrum, while it absorbs nearly the whole of the green rays. The transmitted light passes freely through a red copper or a blue cobalt glass. But if the iodine vapour be sufficiently dense the whole of the red rays are absorbed, and the transmitted rays are of a pure blue colour. They are now freely transmitted as before by the cobalt glass, but will not pass through the red glass. A solution of iodide in sulphide of carbon exhibits a similar dichroism, and according to its density appears either purple or blue when white light is transmitted through it. The alcoholic solution, on the contrary, is of a red colour, and does not exhibit any dichroism.

#### THE ACTION OF HEAT ON BROMINE.

Professor ANDREWS also made a communication on the above subject, of which the following is a brief abstract:—If a fine tube is filled one-half with liquid bromine and one-half with the vapour of bromine, and after being hermetically sealed is gradually heated till the temperature is above the critical point, the whole of the bromine becomes quite opaque, and the tube has the aspect of being filled with a dark red and opaque resin. A measure of the change of power of transmitting light in this case may be obtained by varying the proportion of liquid and vapour in the tube. Even liquid bromine transmits much less light when heated strongly in an hermetically sealed tube than in its ordinary state.

#### REPORT OF THE COMMITTEE OF THE CHEMICAL SECTION ON UTILISATION OF SEWAGE.

MR. J. GRANTON, the chairman of the committee on the Treatment and Utilisation of Sewage, read the committee's report, which stated that, upon its re-appointment at Liverpool last September, it proceeded at once to consider the subjects which seemed to demand immediate attention in furtherance of the investigation which had been entrusted to it. The first steps taken were to endeavour to procure information from the towns where works have been constructed for the application of sewage to land by irrigation; and from the places where the dry earth, or Moule's system, is in operation. Printed lists of queries were sent to a number of towns, but only eight of these answered the circular on irrigation, and one answered the queries regarding the dry earth process. The answers from the towns had been tabulated, and would be found in an appendix. During the construction of the present tanks at Breton's farm in the winter, very accurate observations could not be made, but, nevertheless, during the extreme frost, samples were taken of the sewage and of the affluent water. The temperature of both and also the atmosphere were observed. Similar observations were made at Croydon and Norwood. The observations as to the quantity and quality of the sewage and affluent water had been taken at Breton's farm, with slight interruptions, from last meeting of the British Association till the present time. The times of sowing and planting the several crops had been carefully recorded. The committee had visited several sewage farms, and examined the various methods pursued at them with a view to determining the practical conditions upon which the success of sewage-farming depends. They had samples of sewage and affluent water collected, and made analyses of them. The phosphate process of Messrs. Forbes and Price, had also been examined by a member of the committee, and an analysis of the affluent water from this process was appended to the report. Analysis of the soil which has passed once and twice through earth closets had been furnished by a member, and the manner in which this process is carried on described. An ox which had been fed for the previous twenty-two months entirely on sewage grown produce, was slaughtered on July 15th at Breton's farm, and the carcass examined by Dr. Cobbold, and Professors Marshall and Corfield, in presence of several members of the committee, with a view to ascertain the presence or absence of entozoa in any steps of their existence. The result of the examination was given in an appendix to the report.

Mr. Hope, Dr. Corfield, and Mr. Gilbert supplemented the report by stating a number of facts, the result of the analysis of sewage and soil, and regarding the system on which the sewage farms at Breton's Farm and Tunbridge Wells are conducted—at what expense, and with what success.

Dr. Cobbold's report on the carcass of the ox was read by DR. CORFIELD, and showed that he found the carcass perfectly free from internal parasites of any kind. He attributed this marked negative result to the following circumstances:—(1) The animal did not graze on the farm, but was fed exclusively upon vegetable products cut and carried from the land; (2) the porous nature of the soil and subsoil alike would rapidly carry

off the sewage, and thus ensure the passage of parasitic germs into the soil itself; (3) he noticed on the irrigated portions of the farm a remarkable absence of those molluscan and insect forms of life which frequently play the part of intermediary bearers; (4) the only molluscs he detected were examples of *Succinea putris*, which were obtained in a small pit of water to which the sewage had no access, but these molluscs, when examined after death, were not found to contain any carcarian larvæ; (5) the flaky vegetable tufts collected from the sides of the furrows occupied by sewage currents consisted chiefly of *Batracho-spermum moniliforme*, in the filaments of which were numerous active free nematodes, but no ova of any true entozoon; (6) the sewage had a strong smell of beer, suggesting the presence of sufficient alcohol to destroy the vitality of ordinary parasitic germs, though it was abundantly manifest that the free nematodes had suffered nothing in consequence. The report concluded by a statement for the purpose of guaranteeing the efficiency with which the carcass of the ox had been examined.

After the various reports on this subject had been read and commented on by various gentlemen, they were approved, and the committee recommended to persevere in their investigations.

#### THE PHOTOGRAPHIC POST.

The Abbé MOIGNO read a short paper on the photographic post, as used by the French Government for sending communications, photographed to a small size, between the provinces and Paris, when the latter was besieged by the Germans. The paper stated that M. Dagrón and M. Fernique were sent by the French Government to Tours by a balloon to establish in the provinces a service of photo-microscopical despatches, to be sent to Paris by travelling pigeons. The party arrived at Tours on the 21st November, when M. Dagrón showed the telegraph-master-general of the delegation there a specimen of his photomicroscopy made upon a thin film. The photographs on the film were much preferable to those on paper, both for lightness of weight and easiness of printing. Abbé Moigno showed one of the films as prepared for sending to Paris. It was about the size of one of our railway tickets, and was capable of reproducing twelve or sixteen folio pages of printed matter, or three thousand despatches. The lightness of these printed films permitted eighteen being covered by one pigeon, which gave a total of more than 50,000 despatches, weighing less than *one gramme*. The films were rolled up in the stem of a feather, and fastened to the tail of the pigeon.

#### EXAMINATION OF WATER FOR SANITARY PURPOSES.

MR. GUSTAV BISCHOF, Professor of Technical Chemistry at the Andersonian University, Glasgow, read a paper "On the Examination of Water for Sanitary Purposes."

Several remarks were made on this paper, after which DR. WRIGHT read a short paper "On the Oxydation Products of the Essential Oil of Orange Peel."

#### HEAT GENERATED IN THE BLOOD.

DR. ARTHUR GAMGEE read a report "On the Heat Generated in the Blood during the Process of Arterialisation." He reviewed the various opinions on the subject which had been entertained, and noticed the experiments of Dr. Davy, which he said were probably valueless. On the other hand, Dr. Christison, in his accurate experiments, had ascertained heat was not materially involved during the process of arterialisation. The specific heat of blood was absolutely the same as that of water. Dr. Gamgee described experiments made by himself, several of them in conjunction with Professor Tait. The earlier experiments he made were unsatisfactory, and no positive proof was obtained of the heating of blood when it absorbs oxygen. He then gave a description of experiments made this year with a complicated but improved apparatus. The results were, that an amount of shaking might be performed as to arterialise blood without the temperature being affected; when venous blood was agitated with hydrogen no heating of the blood resulted, but there was always a slight evolution of heat when the blood was shaken with oxygen. Professor Tait, who had repeated the experiments, authorised him to say that they appeared to him to be perfectly correct.

Professor Rutherford, King's College, London; Mr. Ray Lancaster, and Professor Williams, Veterinary College, Edinburgh, made some observations, in which they expressed their sense of the value of the paper. Dr. Gamgee then gave explanations on points suggested by them and by the President, who took exception to the expression regarding Dr. Davy's ex-

periments that they were valueless. The President said that Dr. Davy's experiments should never be so mentioned, and he suggested that the expression should be altered before the report was printed. Professor Allen Thomson further took exception to some of the results arrived at by Dr. Gamgee. In deference to the opinion of the President, Dr. Gamgee undertook to withdraw from the published report the expression as to Dr. Davy which had been objected to. On the motion of Professor Rutherford, the report was received.

#### INOCULATION IN THE LOWER ANIMALS.

DR. JOHN CHIENE read a paper "On an Experimental Enquiry into some of the Results of Inoculation in the Lower Animals." He noticed cases in which cancer had been introduced by inoculation, and described the mode in which he had conducted his experiments. The great majority of cases of inoculation had been made on dogs, animals liable to cancer. A number of cases of inoculation had also been made in the cases of rabbits. The author described the cases of two rabbits particularly. The general result was that inoculation did not produce cancer, but a local disease, not particularly due to cancer, and that this local disease had a tendency to heal by contraction or suppuration.

#### DIETARIES IN WORKHOUSES.

DR. EDWARD SMITH read "Remarks on the Scheme of Dietaries in the Workhouses of England and Wales." He had been engaged in making enquiries into this subject, and the dietaries of prisoners and others fed by the public, and the results, reported to the Government, were contained in various blue books. The food selected in the workhouses were to be those in ordinary use in the several localities, and were to include oatmeal, cheese, and puddings. The kind and quantity of food was to be adapted to the age and condition of inmates. More bread was to be given to growing persons, and less food to women than to men, but the diminution was not to exceed one-sixth. The author described in detail the dietaries which had been adopted in workhouses. It was doubted whether children in workhouses were as healthy as other children, and lately more bread and milk had been given. The results as to adults were satisfactory, particularly now that workhouses were filled by the aged and infirm, and not as formerly, by the unemployed. This was the case in the workhouses to which he referred, but there were many in which the diet was unsatisfactory. In some bread and gruel were always given for breakfast and supper, and not much meat at any time. In the cheese districts, there were cases in which out of twenty-one diets in a week, eighteen were cheese and bread. In other cases meat was given too often—six or seven times a week—and in quantities far beyond the requirements of the body. It was difficult to interfere with local management in this country, but it was desirable to advance to uniformity, with the view ultimately of a dietary scheme being issued by the Government for the workhouses in the kingdom.

#### THE BRAINS OF THE INSANE.

The next paper was by Dr. J. BATTY TUKE, "On the Morbid Appearances Noticed in the Brains of the Insane."

DR. TUKE pointed out the importance of localising brain function, and that the means to this end at the disposal of the physiologist were nearly exhausted. Comparative anatomy had done its work; and experimentation, although it had done much to demonstrate certain leading facts of importance, had left much which was doubtful, and more that it had not attempted to explain. Moreover, sources of fallacy existed in this method of enquiry from the difficulty which existed of localising artificial injuries, and of reaching deep-seated portions of the brain. Disease, however, injured in a finer and more delicate manner than the knife, and it was held that much might be elicited regarding the functions of the brain by observing the parts of the organs implicated in disease, and the perversions of the nervous system which are associated with them. It being generally acknowledged that the intellectual powers are manifested through the grey matter of the cerebrum, and as in insanity these faculties were impaired, exaggerated, or perverted, the author asserted a belief that, by examining the brains of the insane a hope existed of discovering a road for arriving at a solution of the functional difficulty. The time had passed when the term mental disease, insanity, or madness, conveyed to the minds of physicians, the idea that the psyche, the mind or its faculties, were the entities which were the subject of disease. By a process of ratiocina-

tion rather than of demonstration the pathologist had arrived at the conclusion that abnormal physical manifestations are dependent upon primary or secondary morbid changes in the nerve tissue; that insanity is a symptom of disease, not a disease itself, and that in the brain the *materies morbi* must be looked for. Six years ago the author commenced a systematic microscopic examination of the brains of the insane and with this most important result, that in every single instance a marked departure from healthy structure was observed. The process by which the brain matter was made fit for the microscope was related, also a list of twelve different parts of that organ which had in a majority of the cases been examined. The morbid appearances may be classified under the following heads:—Changes—1st, in the neuroglia; 2nd, in the nerve cells; 3rd, in the nerve fibre; 4th, in the blood-vessels; 5th, granulation in surface of cerebral convolutions, &c.; and 6th, amyloid and colloid bodies. After describing the various forms of disease, which were illustrated by diagrams and microscopic sections, the paper concluded with the following statements:—We are not prepared to designate the individual parts of the brain specially affected in different forms of insanity; but we may say generally, that the corpora striata are the portions most frequently found affected, and that the cerebellum is the organ least frequently subject to disease. Further, that the white matter is much more liable to evident structural morbid change than the cortical substance in comparatively recent cases, and that where the intellect has been in abeyance for prolonged periods, the structure of the grey matter of the cerebral convolutions is difficult of demonstration, the layers are found indistinct, as the cells are few in number and generally small in size. We do not wish it to be thought that we have found in cases of insanity any changes in the cerebrum which may not be found in other parts of the central nervous system in diseases not involving the intellect. The seat of these morbid conditions is the great point to be considered in the different cases; and in this direction we propose immediately to direct our attention by analysing the series of microscopic sections at our command, 2nd by carefully comparing the physical signs observed during life with pathological conditions. The great conclusion to which our researches have as yet led us is, that in the fifty-three cases of chronic insanity which we have examined, we have found distinct structural changes in the brain of each. This in itself is a fact having a most important bearing on the physiology of the brain, and one which, if followed up, may be reasonably expected to dissipate much of the mystery which hangs over the functions of its various parts. Our object in bringing this paper before the Association is the hope of enlisting others in an enquiry which is so vast that we feel a host of investigators will be needed to prosecute it.

#### ADMINISTRATION OF THE POOR LAWS.

MR. W. A. PETERKIN read a paper "On the Administration of the Poor Laws," the following being the concluding observations:—In Scotland, outdoor relief is the rule, for twelve at least will receive relief at their own homes for one relieved in a poorhouse. As to the amount and description of relief to be given, I have observed that public opinion is disposed to be liberal until it has to pay, and that it is much easier to censure than superintend the administration of relief. It will be universally admitted that some kind of organisation is a necessity in the administration of relief, and I have come to be of opinion that the smaller the organisation, the better for poor and rich; and that as congregations of worshippers form the smallest social arrangement which we have for a common object, it would result in good to all were it practicable to make each congregation legally responsible for the relief of every poor member, leaving to the care of the present poor-law organisation only those persons who were not members of, or not connected with some religious body. Failing such an arrangement, which may be regarded as Utopian, we have the next smallest arrangement—namely, that of parishes; and therefore in the meantime we are safer to adhere to that than to adopt—what may be more convenient, but which may not be so economical—large areas of administration. It is an advantage of our present system in Scotland that the recipients of relief are all previously well known to, and visited by, inspectors, local responsible officers, controlled by 385 separate boards, representing all interests. To have these boards constituted so as to secure impartial, and intelligent, and humane administration is, in my opinion, of the utmost importance to all interests.

SIR JOHN BOWRING was struck with the novelty of the suggestion that congregations should be charged with the relief of

their own poor ; but he was afraid there would be a difficulty in carrying it out, because in many congregations there were scarcely any poor, and in others there were scarcely any rich. He did not know what had been the effect of the collections for the poor in the congregations of Scotland, but, as far as his experience went, he believed that in England it was not advantageous. In the first place, there would always be favourites of those who dispensed the charity, and it would also be found that the least intrusive of those who required relief would be passed over. In the examination of cities they would often come across instances of extreme misery, which no prudence could have prevented. He knew of the wife and children of a minister being found in the greatest misery. They were too proud to unfold their distress.

REV. J. F. BATEMAN thought that in England they ought to be grateful for the Union Rating Bill, because it tended to do away with close parishes, ensured the consideration of all applications for relief by the whole body of guardians, and at the same time the rates were spread over the whole union.

MR. LAMPORF said it was of importance to consider the spirit in which the Poor law was administered. When the guardians looked upon the paupers as their natural enemies, and upon themselves as the guardians of the parish purse, and not of the interests of the poor, the evils of pauperism were not only extended but greatly aggravated. They looked too much to the increase of their expenses in relieving the poor, which he did not think was caused by the increase of pauperism. Throughout the whole of the empire it would be found that the ratio of the increase in pauperism did not progress so fast as the ratio of the population, and therefore to take the amount of the poor rates as indicating an increase of pauperism was a mistake.

MR. A. E. MACKNIGHT said that before 1845 the Scottish poor law was practically voluntary. Since that date it had been made compulsory, and the question came to be, whether they were better off now than previous to 1845. He was of opinion that if this subject was looked upon in a large point of view, it would be seen that, so far from the poor having been benefited in Scotland by the Act of 1845, they were now worse off than before. If this were true, that the poor had not been benefited by that law, the question was, whether they should not go back to where they were before 1845. It was then the practice to have collections in the congregations of different churches ; and with a little assistance, these collections were found sufficient to support the poor in more comfortable circumstances than those in which they were now placed. Dr. Chalmers, by means of this congregational system, succeeded in making the poor of one of the worst districts of Glasgow infinitely better than they had been before. In reference to the burdens on property, he might mention that it was a serious question with some small proprietors whether they would not have to abandon their properties in consequence of the increase of the poor rates.

MR. HIRST, Bedford, said, taking the country as a whole, he did not think the rates had increased in a greater degree than the population ; and if they compared the present time with something like twenty years back, they would find that the value of money was from 20 to 25 per cent. less than it was at that time. The Union Assessment Bill had done a great deal of good, but it had not been such a benefit as he expected. He thought a large number of cottages would have been built, but he found that since the passing of that Bill the increase in the number of cottages was not considerable. He believed the Union Assessment Bill did not have such a good effect in one respect. Formerly, when the chargeability of the poor was confined to the parishes, a great effort was made to obtain employment for the poor people of the parish ; but now that the area was extended over the union, the people in the different parishes did not have such a direct interest in providing work for all the poor people. But whatever might be said to the contrary, he believed the poor laws were fairly and well administered throughout the country. He did not think the feeling of the guardians to reduce the rates carried them beyond what was fair and legitimate. Many infirm and partially infirm persons were able to do a little for themselves in their houses, and a little assistance from the Board enabled them to maintain themselves comfortably ; but if this system of out-door relief were abolished, these people would be shut up in work-houses, and they would then be far more burdensome on the ratepayers.

LORD NEAVES said it was not the case, as one of the gentlemen remarked, that the incidence of the poor tax was

entirely on landed property. It was divided between owners and occupants. And with regard to what had been said about the amount of the poor rates, he confessed that he had not heard of any proprietors who were meditating the relinquishment of their property. He confessed he could not understand Mr. Macknight's idea of going back to the old law. Dr. Chalmers did a great deal for his parish, but he was a man of transcendent eloquence and force of character ; and unless every parish had a Chalmers in it, and was free from dissent, he did not see how that plan could be worked out. In every town there were generally five sects—Establishment, Free Church, Episcopalians, United Presbyterians, and some others.

## THE THIRTY-NINTH ANNUAL MEETING

OF THE

## BRITISH MEDICAL ASSOCIATION,

*Held at Plymouth, August 8th, 9th, 10th, and 11th, 1871.*

President: JOHN WHIPPLE, Esq., F.R.C.S.

THE first general meeting was held on Tuesday, August 8th, at 8 p.m., Dr. Charlton (Newcastle), President for the past year, in the chair. A deputation of the Corporation of Plymouth was introduced by the mayor, Mr. Serpell, and a congratulatory address was read by the Town Clerk, Mr. Whiteford. Dr. Charlton made a short speech in acknowledgement of the compliment. Dr. Charlton then delivered a brief valedictory address, and gave a short account of the incidents of his year of office. He remarked that Medical reform had been hoped for, but in this case the Association had been disappointed. The Government had left the matter in the hands of private Members, but the result had only confirmed the belief that no reform would be acceptable to the profession which did not recognise a "single-portal system," and also give representation to the main body of the Profession. He then introduced Mr. Whipple of Plymouth as President of the meeting, with a few well-turned phrases of laudation.

MR. WHIPPLE, F.R.C.S., assumed the President's chair amid considerable applause, and delivered his

### INAUGURAL ADDRESS.

He commenced by remarking that with an inaugural address of that description there must ever be a certain amount of difficulty in the selection of a subject. So many branches of science invariably presented themselves to the mind's eye, on either of which it would be tempting to dilate, that it became a bewildering task, if not an invidious compromise, to discriminate between their respective claims. The dilemma could only be successfully evaded by the simple process of rejecting both alternatives, and by wandering away to other scenes, where might be found some neutral spot unassailable by either objection. Surely no one could cavil at the soundness of that political economy which recommended emigration to a more distant locality, when the homestead was overstocked, and the neighbouring district tenanted by more enterprising and better qualified competitors. Should any other apology for his selection of Plymouth as the subject of this address be deemed necessary, he should simply rest it on a personal and professional ground. He would pay a grateful tribute alike to the town itself, and to the strangers it welcomed, by reminding them that they were treading on historical soil, and that there were many special features of interest associated with its past history, which were too often forgotten in the whirl of present sensation, or were shorn of their real value by the curious, yet fashionable propensity of subordinating home scenes and antecedents to those of a purely foreign extraction. On the other hand, professional experience abundantly testified that the mind cannot bear too heavy a strain, or digest at once more than a fair proportion of substantial or stimulating diet. Keeping that in view, he found his course more accurately defined. It was to send them forth to the duties and details of their respective sections with their digestive faculties unwearyed, and their mental grasp unim-

paired by any homœopathic treatment of his own. If it were true that the science of agriculture depended much on a due application of the rotation of crops, they should not be far wrong in adapting a similar principle to an analogous field—the human mind. In both cases the sure condition of an ultimate return was a judicious appreciation of, and a proper deference to, those elements which might not inaptly be termed the surface and hidden depths of their respective systems. As with the field so with the mind, a summer's fallow might have its advantages, and the crop of sprightly tares turn out no mean preparation for an ample yield of weightier cereals.—Mr. Whipple then proceeded to give a succinct and interesting sketch of the history of the town from the earliest period down to the present day. Special reference was made to the Elizabethan period. Carew said of it, "Here mostly have the troops of adventurers made their rendezvous for attempting new discoveries and inhabitations; as Thomas Stukelcigh, for Florida; Sir Richard Grenville, for Virginia; Sir Humphry Gilbert, for Newfoundland; Sir Martin Frobisher and Master Davies, for the north-west Passage; Sir Walter Raleigh, for Guiana." Thus, in the field of geographical exploration *facile princeps*, Plymouth might well rest satisfied with such associations were there not other considerations, practically of greater value, which really outvied them. If it were a far higher effort of genius to consolidate the fruits of victory than to organise a superficial and resultless triumph over hostile combinations, and pioneers of the colonial system—those men of iron will and daring hardihood who first settled in the newly-discovered continent—must ever occupy a loftier niche in the temple of fame than even those hardy adventurers who ploughed a pathway through the waste of waters to its unknown shores. It was from Plymouth—and under the auspices of Devonshire men in the reign of Elizabeth—that the first colonizing expeditions set sail; and though they were not successful in the attempt to form permanent settlements, yet it was from these sources that they traced those subsequent results which had had such a marked influence on the destiny and civilisation of the whole world. But not only in the comparatively peaceful field of adventure did Plymouth win its laurels at this era. These were portentous times—times, without a doubt, when British alarmists had no unsubstantial grounds for gloomy prognostications. And the thunder-crash came at last. England must be annihilated; and with the haughty arrogance of assured victory, the gigantic Armada was launched forth for its destruction. He need not dwell on the oft-told tale of ambition crushed, and the Invincible destroyed. Let him rather introduce them to a scene which, striking in itself, might, from its local associations, not be so familiar as the sterner details of history to the majority among them. In the year 1588 there was a great gathering at Plymouth. Men had not met together to wander hand in hand in peaceful rivalry over the fertile fields of science. They had met for action—sharp, prompt and decisive; and there was an unmistakable rough and ready look about them which was exactly in keeping with their purpose. If they failed to detect it at the present moment, let them rather congratulate themselves on an alteration of circumstances than indulge in querulous repinings on the evidence of national decay. But the Armada was expected then, and the British fleet was lying in Catwater. For a nation that somehow had the reputation of never being exactly ready for an emergency, it was satisfactory to remember that on this occasion a fleet was actually prepared, and impatiently waiting for the expected collision. At Plymouth were assembled all those great captains of the age whose renown is imperishable—Raleigh and Sheffield, Grenville and Howard, Francis Drake and John Hawkins, Martin Frobisher, John Davis, and a host of others on the watch for earliest information with respect to the movements of the hostile armament. Somewhere about the site of the present citadel, there stood in those days the "Pelican Inn," very likely so called after Drake's famous ship wherein he circumnavigated the world. Behind it was a small bowling-green, where, in friendly pastime, they could while away the long, tedious hours of their protracted suspense, whilst in front of it they could command a magnificent view of the sound, and descry the earliest approach of friend or foe on the distant horizon. And there the men on whom England relied in her hour of extreme peril were actually collected—thus were they engaged when the long anticipated intelligence of the Armada's approach at length arrived. How they acted in

the emergency was aptly illustrated by Drake's terse rejoinder—"There is time enough to play the game out first and thrash the Spaniards afterwards."—Passing on to the time of the Civil War, Mr. Whipple remarked that Plymouth's stubborn and consistent support of the Parliamentary Cause was entitled to praise for its unwavering fidelity.—Pointing next to the quick declaration of the town in favour of William of Orange, and the foundation of Plymouth Dock, he referred his hearers for further information to Worth's "History of Plymouth," a work published by an author to whose researches he was personally indebted for much information.—As a matter of Medical interest, however, he called attention to the fact that the pavilion system of constructing hospitals, now so much in vogue, had its origin at the Naval Hospital at Stonehouse more than one hundred years since, which was spoken of by M. Zenon in 1777 as the most perfect then existing.—Mr. Whipple concluded by saying:—"Such an assemblage as the one before me must leave its mark on the future history of Plymouth, if it be instrumental in calling our attention to those shortcomings of which we are willfully ignorant or tacitly conscious. Once recognise our defects, and a most important step has been taken towards their amelioration. That there is nothing so successful as success is a truism we cannot refute; but success, be it remembered, is never so permanent as when it is evoked from the ruins, and established upon the basis of an admitted failure. If this result be attained by your co-operation, either in awakening our emulation, or in giving an impetus to latent talent, as yet crippled and confined from its never venturing to soar beyond mere local associations, or from its shunning the friction which can only give it an enduring polish, it will add the element of permanency, though not an increase of cordiality, to the welcome which I now bid you to Plymouth."

The usual votes of thanks were carried, and the Hastings medal was then presented to Dr. J. M. Pothergill, of Leeds, for his essay on Digitalis.

The report of the Council, 1871, was then read.

The Treasurer's report showed that the income of the Association in 1870 was £5,261 16s. 2d., including a balance in hand of £13 7s. 11d.; the expenses £5,223 13s., leaving a balance with the Treasurer of £28 3s. 2d.

After a discussion the adoption of the report was then put and carried by a large majority.

On Wednesday a public breakfast was held at the Royal Hotel, Devonport, after which the members dispersed to visit the dockyard where H.M.S. *Agincourt* was an object of general interest, to inspect the Royal Albert Hospital, and to witness the parade of the troops.

At eleven o'clock the Second General Meeting was held in the Town Hall, Devonport, when a congratulatory address was made by Mr. Joseph May, F.R.C.S., the Mayor of Devonport, and the Town Clerk, Mr. T. Woolcombe, read an address from the Corporation, and Mr. Whipple, the President, returned thanks.

It was then announced that Birmingham had been selected as the place of meeting for 1872, and that Mr. Alfred Baker was the President elect. Mr. Baker briefly returned thanks for the honour.

Mr. HUSBAND, the President of the Council, referred to the election of a secretary, and announced that the Committee of Council had agreed that Mr. Williams should continue in office for the remainder of the year at £200 instead of £150 for the half-year. He proposed a vote of thanks to Mr. Williams for his past services of eight years. Dr. Falconer, the treasurer, seconded the motion, which was carried after a few words in support from Mr. Gamgee and Dr. Stewart. Mr. Williams briefly returned thanks.

DR. GEORGE JOHNSON delivered the Address in Medicine, in which he suggested that a belief in the power of Nature to cure all curable diseases is inconsistent with a disbelief in the existence of morbid processes having a conservative or curative tendency. He indicated various pathological phenomena, the conservative tendency of which appeared to him indisputable; and endeavoured to show that, by a careful study of the functional and structural changes which result from disease, we may obtain most valuable indications for treatment—learning thereby both to do that which may aid nature, and to avoid such means as may tend to thwart and hinder the natural curative processes. He added, again, I have intimated that it is difficult, and, as it seems to me, impossible, to reconcile a disbelief in the elimination of morbid poisons with a belief in

the spread of disease by contagion. Confirmatory evidence as to the elimination of morbid poisons is afforded by the disastrous results of repressive methods of treatment. To take all possible precautions to exclude the cholera poison from the system, and then, when once it has gained an entrance, to endeavour to retain it there by opiates and astringents, are practical modes of procedure utterly inconsistent with each other; unless, indeed, the object of this repressive treatment be to sacrifice the individual for the public good—to prevent the patient, at the peril of his own life, from scattering the seeds of disease and death amongst the community. He believed that the success of our attempts to cure and to prevent disease depends mainly upon an exact diagnosis and discrimination of the various forms and shades and stages of disease; upon a correct interpretation of pathological processes and symptoms; a careful avoidance of erroneous and misleading theories; and, lastly, upon a prompt recognition of the exciting causes of disease, some of which may be avoided, some removed, while the influence of others may be in a greater or less degree counteracted by the timely employment of suitable means.

In the afternoon the Sections of Medicine, Surgery, and Midwifery concluded their sittings at the Royal Hotel.

In the evening the members of the Association were entertained at a brilliant *soirée* by the President, Mr. Whipple, at the Royal Hotel.

On Thursday the third General Meeting was held at the Royal Hotel, when Professor Lister delivered the Address in Surgery, the subject of which was "The Antiseptic System of Surgical Treatment."

In the evening the public dinner was celebrated.

### THE GOVERNMENT AND THE PROFESSION.

WE regret to be compelled to return to this subject, but the debate on Foreign decorations last Friday in the House of Commons leaves us no alternative. It was proposed to permit officers to wear Foreign orders conferred for services under the Geneva Convention. When this was carried the Premier interposed, and took the sense of the House a second time by which the matter seems to be left to the Government. We do not expect to regret this. It only brings into more striking relief the injustice of Government to the Profession on which we commented

last week. Drs. Wyatt and Gordon, who represented England in Paris during the siege, have, amongst others, been created officers of the Legion of Honour. Of course, they cannot wear their decorations, nor do we think that to permit them to do so would be a worthy acknowledgement of their services. We repeat what we said last week, that these men ought to receive the rewards of their arduous services from the British Government. This week another of Her Majesty's subjects has received a baronetcy. Richard Wallace, who staid in Paris and did so much good with his wealth, has most properly been thus rewarded; but the two Medical Officers who were in Paris *officially* are still unrecognised. Why? Is it because they were *Medical* men? If so let the public learn that the Army is running the risk of being deprived of first-class men in future. Once let it be known that Army Surgeons will not receive the rewards given to other officers and the attractions of the service will be so diminished that there will be fewer candidates than ever.

Promotion has been freely accorded to so-called *combatant* officers, who were sent to the Franco-Prussian War, but were never in any danger at all, being comfortably located at the Head-quarters of Armies in the field. Gordon and Wyatt, *mere Medical Officers* in Her Britannic Majesty's Army, suffered the horrors and dangers of the Siege of Paris; were present on several battlefields, giving the aid of the most skilful British surgery to the wounded—doing this as a matter of duty. So the British Government leaves them to the enjoyment of the consciousness that they have done their duty, and promotes and decorates those who have not made the great mistake of devoting their lives to curing instead of killing. We repeat our protest against the neglect with which the Profession has been so long treated, and we appeal to the country as to whether the public services is not injured by the studied neglect of so important a branch as its Medical Officers.

As we said last week, these men ought to be promoted. The Deputy Inspector should be gazetted Inspector; the Surgeon Major should obtain a similar reward. We are told that promotion in the Guards cannot be given. Then let Wyatt have at least a C.B.; and, if the country is in so beggarly a condition that it cannot afford Gordon the pay of Inspector, give him *brevet* rank, or offer him to go on half-pay as full Inspector, and give him the next step in his order, converting his C.B. into a K.C.B.

---

### THE FINANCIAL BREAK-DOWN IN THE BRITISH MEDICAL ASSOCIATION.

It is just now one of the exigencies of Ministerial service that Governments should have tough hides, impermeable alike to hard blows and pointed sneers. The Minister of the present day is not, as he used to be in old-fashioned conservative times, the touchy individual who maintains the perfection of his administration and throws up his office the moment the breath of censure lights upon him. In our day our responsible rulers listen complacently and smilingly to the catalogue of the failures of all departments of their administration, and receive the sneers, taunts, and revilings of their opponents by a frank admission that their administration has failed, their policy is unpopular, and their schemes impossible, but that, nevertheless, they mean to hold their seats until they are absolutely kicked out of office.

The Council of the British Medical Association confess to an unhappy resemblance to the Ministry in this respect, and, as far as their present attitude foretells their actions, they certainly appear quite as thick-skinned as their exemplars.

With admirable *nonchalance* they presented their constituents at Plymouth with a narrative of the disastrous down-break of their management of the Association, and received the unequivocal hint of the meeting that their administration was no longer grateful or beneficial to the Association, with a smiling determination to keep the job in their own hands whether the Association liked it or not.

To our mind their Financial Budget should have been enough to disgrace their management, but its features have become so much a matter of course to the Association that it attracted little attention. It seems the Association received an income of £5,261 last year; of this very large sum, a sum capable of achieving great benefits for the Profession, nine-tenths was at once absorbed by the Association journal, which actually cost for its production £4,664. The crumbs which the journal dropped from its all-absorbing mouth were snapped up by the secretaries' department, and out of this princely income just £60, or about a hundredth part, was afforded for the advancement of science.

We cannot conceive how such a financial fiasco is allowed to pass without due consideration of the members even when the Council, duly drilled by the journal, has certified such a state of things as quite correct.

An experience of very many years of journal management enables us to say that the managers of a journal which receive an income of over £5,000 a year ought, with the utmost margin for liberality of management, return to its proprietors at least £1,500 a year. What would any publisher in the world think if he found that so valuable a *clientelle* was barely self-supporting. He could not fail to know that on the most charitable explanation gross extravagance of management existed, and would no doubt take care that the owner of the journal would at least have a little share of the spoil.

But the Council of the Association, with such a balance sheet in their left hand, have presented with their right a still more unsavoury dish. Here it is in their own words.

"The mode in which the business of the Association has been carried on, and especially the absence of supervision over the business and monetary transactions of the journal office, has been for some time far from satisfactory. The Council appointed a Sub-Committee, and the inquiry elicited amongst other matters that from a want of supervision at the journal office the clerk and collector had been able to mis-appropriate a large sum of money."

A more humiliating and discreditable confession we never read. It amounts to no less than that the Council had blindly entrusted the control of an income of over £5,000 a year to dishonest servants and incompetent supervisors; that the editors and official staff, which cost the Association nearly £1,000 a year, were not even to be expected to prevent such a malversion of the funds.

In our opinion a Council handing to its constituency such a pitiful confession should have handed their resignation with it. Have they done so? Have they brought the responsible officers to the block? Have they dismissed or even reprimanded those who failed to detect such a condition of things? Not at all.

True to the instinct of cliquism and subserviency, which has been the animating spirit of the Association for some years, they have handed over the body, bound hand and foot, to the control of those whose neglect made such defalcations possible. Such infatuation in the conduct of a commercial enterprise, such as the Association now is, can have but one result.

What has occurred once will, under the same regime, occur again; and one more such balance sheet must cost the Council its seat and the Association its integrity.

### THE SCIENTIFIC CONGRESS.

SCOTLAND is again to the front. What with the Scott-Centenary and the British Association for the Advancement of Science, with the Pharmaceutical Conference in its wake, Edinburgh has stood out in bold relief as the most active spot in the dull month of August. The lesser luminary, the Medical Association, instead of following the greater Congress has chosen to fix its meeting at the extreme South, and thus while competing as jealously for the interests of its supporters made its feebleness still more patent to all who think about it.

With every wish to be faithful to our art we could not give up the scientific world for the branch that demands our attention all the year round, and our own columns from which we are compelled to exclude so much that is highly interesting, fully justify our course. We provide our readers with reports of certain papers that make the most demand upon them. Here we can only refer to some other points.

First of all the third Edinburgh Meeting of the Association will be remembered as the one at which was mooted a question over which we have often pondered—viz., whether it would not be practicable to give these meetings a more permanent place, and to unite by some tie the places which have been visited. Possibly local societies might be planted and confederated together of which the British Association might be the centre. There is no doubt a danger lest the Association should be deprived of some of the interest taken in it; but there is a possibility of much good being effected. "A Visitor" this year has enriched the columns of the *Globe* with one of the best descriptions of the meeting. On this question he writes:

"There is no necessary undervaluing of local efforts implied in this proposition. The purpose would be, as has been said, 'to consolidate and organise rather than to supersede these local efforts.' Acting as a general superintending agency the Association would be able—in the arrangement, for instance, of scientific lectures—to prove of great practical service, and would impose a check upon useless or purely mischievous schemes. The general union which is thus suggested would also, it is expected, be the means of connecting together the various scientific societies, clubs, and museums in different parts of the country, and of connecting all of them with a central body, and it can hardly be questioned that great good would probably result from such a co-operation and conjunction. It is further believed that in this way the British Association might come to exercise a considerable political influence, which would be useful in enabling them to press upon Government and Parliament the various matters of legislation which science declares to be valuable or essential to the well-being of the community. There is no need for the creation of any new central organisation for the purposes in question. They might all be effectively fulfilled through the medium of the organisation already existing, if only its energies and efforts were properly directed and

adequately responded to and met. It will not be the least important achievement of the present meeting of the British Association if it should have conduced to the carrying out of the plan thus proposed by some of its leading members."

We can heartily wish success to any scheme of the kind although we would whisper a warning to the promoters not to adopt any details that might tend to bring the great Congress down to the level of the Medical Association.

The 1871 Meeting was further remarkable for the interest excited on questions relating to spontaneous generation, Darwinianism, and other topics, that have lately provoked so much controversy. The able address of the President of which we gave a full abstract last week started these by the theory on which he ventured to account for the origin of life, and respecting which we may quote the able writer before cited:—

"Holding, as 'an article of scientific faith,' that life can only come from life, and that there is, therefore, no such thing as spontaneous generation, he ventured to suggest as a possibility that life may have originated on our earth 'through moss-grown fragments from the ruins of another world' which had been dashed in pieces in space, and from which the seeds of life were borne in particles of stone or rock, that alighted on the earth just as meteoric stones fall even now upon our globe. It must be said that the hypothesis does seem 'wild and visionary.'"

Those interested in the subject will find the Address in full, and also full reports of the various papers and of the discussions they elicited in the numbers of the *Edinburgh Evening Courant* published during the Congress, and the Editor of which habitually discusses in the best spirit some of the foremost scientific questions of the day.

## Notes on Current Topics.

### Sanitary Reforms and their Beneficial Results.

A RECENTLY issued return supplies satisfactory evidence of the good that can be done by well applied energy and organization. The unhealthy condition of Calcutta, the filthy state of the houses occupied by natives, and the practice which had converted the Hooghly river into the most disgusting of sewers have long been known and deplored. The Calcutta Municipality have, however, during the past few years dealt vigorously with the evils, and their success is gratifying to themselves and encouraging to sanitary reformers everywhere. It appears that there has been marked improvement during the past six years. The mortality returns for each of those years show a continuous decrease of deaths, and the mortality in 1870 was considerably less than half of what it had been in 1865. Thus in the last-mentioned year, 1865, the total deaths were 23,242, in 1866 they were 20,283; in 1867, 12,097; in 1868, 13,733; in 1869, 12,795; and in 1870, only 10,102. A compulsory system of removal of filth from private houses met with considerable resistance from natives, who had been accustomed to pay little heed to cleanliness or decency, and were indisposed to bear the slight pecuniary charge which a daily removal entailed. The practice of casting the carcasses of dead animals into the river has been prohibited, and all such carcasses are now taken to a remote place, where they

are skinned and cut up, and within an hour "the bare bones only remain, so completely and rapidly do the vultures, crows, and jackals discharge the duties required from them." Perhaps the greatest improvement introduced into Calcutta has been the water supply which was brought into operation during the past year, and which, notwithstanding gloomy anticipations of caste prejudices, is readily accepted by all class of Hindoos.

### Therapeutic Value of Gelseminum.

GELSEMINUM (or, as it is sometimes written, gelsemium) is of late attracting considerable attention. It is highly lauded by some practitioners as a nervous sedative, in cerebral congestion, mania, and a great variety of disturbances resulting from disorder of the nerve-centres. We (*Pacific Medical Journal*) know of one physician who regards it as invaluable in nervous or sick headaches; ten or fifteen drops of the tincture to be given three times daily. The physiological effects of the agent are very remarkable. Even moderate doses will sometimes produce a peculiar, heavy sensation in the forehead, with partial paralysis of the levator muscles of the eyelid, so that it is difficult to keep the eyes open. We have employed it frequently for a number of years, often with benefit, but certainly not with such happy results as some others ascribe to it. The following formula will be found valuable in hysterical and functional disturbances of the nervous system:

R. Tinc. valerianæ ammon., oz. j;

Tinc. gelsemini, dr. j.

M. Sig. A teaspoonful p. r. n.

Some of our druggists prepare an ammoniated "elixir" of valerian, which is better than the officinal tincture, in being much less disagreeable.

### Medical and Surgical Memoirs of the Confederate Army.

PROFESSOR JOSEPH JONES, of the University of Louisiana, is engaged in preparing an elaborate treatise on the Diseases of the Southern States, the result of fifteen years' assiduous labour, including the experiences of the recent civil war. There will be two volumes of one thousand pages each, which will be issued as soon as a sufficient number of subscribers shall have been secured to defray expenses, and furnished at actual cost. Dr. Jones, it is well known, is capable of making this a highly valuable work. He writes to the *Pacific Medical Journal* as follows: "At present I am engaged in preparing for the press, the labours of the past fifteen years. These investigations were undertaken for the advancement of the Medical Profession, and they have been prosecuted at heavy cost of time, money, and health; and I hope that the Profession will sustain me in the effort to place them in a living form. You will oblige me by directing the attention of your medical friends to the subject."

### Physiological Action of Camphor Inhalations

We have lately met with a lady, writes the Editor of the *Pacific Medical Journal*, aged sixty-five years, who exhibits a sensibility to the action of camphor, which is worthy of note. She is subject to spasmodic twitchings and distressing nervous paroxysms, which prevent sleep. Under these circumstances, she pours some spirits of

camphor on a napkin and snuffs the vapour, which acts with the promptness of chloroform as a sedative. That a powerful impression may be made on the nervous system by the inhalation of camphor in alcoholic solution, is very easily demonstrated by experiment on one's own person. The etherial solution is worthy of trial.

### The Social Evil.

THE *Pacific Medical and Surgical Journal* for July contains a well-written communication under this head, which the Editor of that able journal thinks presents a highly plausible argument in favour of the system of licensing prostitution. But the experiment referred to has not been long enough in operation to test its efficiency. In other parts of the world, says the Editor, where the system has had a fair trial, it does not appear to have restrained either prostitution or disease, but simply turned them into hidden channels. During a detention in Panama, twenty-one years ago, the writer had an opportunity of witnessing a common mode of "cleaning up" around the back doors of houses, where all manner of filth was habitually deposited. Instead of removing the offal, the adroit scavenger brought sand in a wheelbarrow and covered it so as to give the appearance of perfect cleanliness. Such, we apprehend, will be the result of all movements against prostitution which involve its legal sanction.

### Veratrum in Large Doses in Convulsions.

DR. HERBERT HEARN, of Brooklyn, in the *Amer. Jour. Obstetrics*, for May, treats puerperal convulsions with veratrum viride in doses ordinarily regarded as poisonous. He uses it as a substitute for the lancet, and in such cases as would seem to require blood-letting; giving from half a drachm to a drachm of the tincture every five, ten, or fifteen minutes, till a decided impression is made on the pulse, and keeping the pulse down to near fifty, until the tendency to convulsion has passed away. Four drachms in twelve hours was given in one case; five drachms in ten hours in another; five drachms in four hours in a third, with uniform success. Vomiting sometimes results, but not commonly. Convalescence is rapid and perfect, without prolonged feebleness. He uses it also in convulsions of children, using from five to ten drops for a child of two years. In the instance of a child of that age, to whom he gave, by mistake, ten drops fluid extract, the convulsion ceased in ten minutes, and the patient made a good recovery. In most of the cases detailed, bromide of potassium, chloroform, and other sedatives were also employed before or after the veratrum, and sometimes with it; but it is evident, from his statements, that the curative results were derived mainly from the veratrum. He believes that the medicine has a direct effect on the spinal cord, but that its primary influence is on the ganglionic or sympathetic nervous centres.

### Edinburgh University.

On Tuesday, the 1st, the annual ceremony in connection with the conferring of degrees in medicine took place in the Music Hall. Thirty-three gentlemen were "capped," and several honorary degrees in laws were also conferred. Dr. Bennett, as promoter for the year, delivered an address.

### Cholera on the Tyne.

THE visit of Mr. Netten Radcliffe to Liverpool, Birkenhead, and to the Eastern ports has already borne good fruit, by producing for the first time united action on the part of the local authorities of all parts of the Tyne. Mr. Radcliffe convened a meeting of these authorities. The Mayor of Newcastle presided. It was eventually resolved:

"That an inspection should be made of vessels arriving from suspected ports.

"That a floating hospital should be at once provided.

"That the expenses to be incurred with reference to cases occurring afloat should, in whatever nuisance authority they may arise, be defrayed by the contribution of every nuisance authority on the banks of the river in proportion to the rateable value of each district."

It may reasonably be expected that the precautions thus promptly taken may serve to exclude cholera from the Tyne; and, in the event of its importation, they will certainly enable the danger to be met in the most economical and efficient manner.

### The Surgeoncy to the City of Dublin Hospital.

DR. WILLIAM THORNLEY STOKER has been elected to the vacancy in the Medical staff of the City of Dublin Hospital. Mr. Purser, who recently succeeded his uncle, Dr. Geoghegan, in the hospital, having taken the place of the late Dr. Hewitt, as physician to the hospital. Dr. Stoker is the son of the late Mr. Stoker, of Dublin Castle, and has been for some time popular as a demonstrator in the Royal College of Surgeons.

### Bequests to Dublin Charities.

WE learn that certain of the Dublin medical charities receive by the death and the benevolent will of Mr. Mullins, of Fitzwilliam square, very acceptable bequests. That gentleman has, we understand, demised £1,000 to the Hospital for Incurables, £500 each to St. Vincent's, Jervis street, and the Mater Misericordia hospitals, and the residue of his fortune, amounting to over £10,000, to trustees for the purpose of building a convalescent home.

### Cholera in Russia.

A WELL-INFORMED correspondent dating 5th inst., assures us that in Moscow and the towns near the old capital the epidemic is very severe. There were sixty-nine new cases and thirty-three deaths in Moscow on the 1st inst. This brings, he says, the total mortality of the epidemic to more than 1,600 out of more than 3,500 cases.

At St. Petersburg the epidemic is reported to be abating, but we notice in the last official return thirty-three new cases, and eighteen deaths with 476 cases under treatment.

The epidemic prevails in many provincial towns; in some it is of a very severe type, and seems spreading in the Prussian frontier.

At the court of the governors of the hospital for consumption, at Brompton, on Thursday afternoon, it was stated that Dr. Frederick Roberts had been appointed to the vacant post of assistant physician. A memorial gift of £500 from the Viscountess Jocelyn had been received, and a ward had been named after her deceased daughter.

### Metropolitan Water.

It must be difficult to judge whether the Water Bill will pass this year, for the various organs of public opinion are quite divided on the point. We shall attempt no prediction but content ourselves with an account of the recommendations of the Select Committee which was reported on the Bill No. 2.

To understand the matter it is necessary to bear in mind that the supply of water to the Metropolis is at present provided by eight water companies, severally formed under special Acts of Parliament, and whose powers and duties are regulated by the general measure, The Metropolis Water Act of 1852; and that the object of the Bill referred to is to secure to the inhabitants of the metropolis:

"1. Distribution of water on a system of constant supply.

"2. Good quality of the water.

"3. An audit of the water companies' accounts, the main object being a distribution of water on a system of constant supply when any defined district is prepared with the necessary fittings."

We ought not to forget that under the Act of 1852 it was ordered that a constant supply should be given from 1857, but that "twice seven tedious years" have passed without London enjoying this boon. Water is now distributed throughout the Metropolis on the intermittent system—that is, it is laid on for a limited period from day to day, the occupiers of houses storing, as they best can, a sufficient supply to last during the intervals of intermission, and it is obvious that such a system presses with especial hardship upon the occupiers of inferior houses unprovided with adequate means for the storage of water.

The Select Committee have considered with regard to the supply of water referred to them by the House.

"1. Report of Royal Commission on the Prevention of the Pollution of Rivers, 1866.

"2. Report of Committee of House of Commons on East London Water Bills, 1867.

"3. Report of Royal Commission on Water Supply, 1869."

The Committee admits that these reports uniformly point to the advantages of a system of constant supply in the distribution of water; and the evidence taken in the progress of the inquiry confirms that conclusion.

How then is it that we have not a constant supply? Simply that a clause in the Act to which we have referred exonerated the Companies from supplying it until four-fifths of the owners or occupiers had asked for it *in writing*.

The Bill before the House proposed to make a change, and has excited twofold opposition. The Metropolitan Board of Works have appeared as opponents, on the ground that the Bill does not go far enough in recognising municipal authority, while the eight water companies have opposed it on several grounds, mainly because it invests the Metropolitan Board of Works with powers to which they object.

The Committee now propose to enforce the provisions of the Act of 1852, and they have endeavoured to facilitate their being carried into effect by substituting the demands of the municipal authorities for the requisition of four-fifths of the inhabitants for constant supply. They are of opinion that the municipal representatives of the people are best able to decide when and where a system of con-

stant supply is required within their jurisdiction. But they have not thought it right that the judgment of the municipal authorities should be absolute, and they have therefore provided that it should be subject to appeal on the part of the water companies to the Board of Trade.

Besides this the Committee contend that the companies should not be obliged to supply water on the constant system to districts unprovided against waste.

The Committee therefore propose to exempt the companies from the duty of providing a constant supply in districts in which one-fifth of the premises are not supplied with proper fittings for preventing waste. These proposals reduce the measure before us to one of those compromises of which the English people seem so fond. May we not therefore hope that after a time the Metropolis will really possess a constant supply of the first necessary of life?

### Small-pox.

We have chronicled from time to time the progress of small-pox, and offered such observations as the facts named seemed to us to call for.

The summary that has been published of its ravages in the official returns will interest our readers.

The present epidemic of small-pox, which may be said to have broken out in the last three months of 1870, caused 1,229 deaths in England and Wales during that quarter. In the first three months of this year they rose to 4,903, and in the quarter ending June last they further increased to 7,012. Of these, 3,241 occurred in the metropolitan division, 1,120 in the north-western counties, and 1,069 in the northern counties; the remaining 1,585 were distributed among the seven other registration divisions. It will thus be seen that the principal centres of infection were the same four that were noticed in the Quarterly Return for the first three months of this year:—London, from which the disease spread into the extra-metropolitan portions of Middlesex, Surrey, and Kent, and also into that part of Essex adjoining the east-end of London; Liverpool, from which the infection extended to a considerable number of the other towns in the densely populated Lancashire district, including Manchester, Salford, Bolton, and Wigan, and also, but slightly, into Birkenhead. The third principal centre of infection was the coal districts of the north, more notably the towns of Newcastle, Sunderland, Stockton, and Durham. The fourth distinct outbreak was in the mining districts of South Wales. In London the deaths from small-pox increased from 2,400 in the first to 3,241 in the second quarter of this year; in Lancashire and Cheshire they declined from 1,224 to 1,120; they rose in Northumberland and Durham from 461 to 1,022; while in South Wales they declined from 207 to 109, although the fatal cases had increased in Swansea. Of the other and smaller outbreaks which cannot be directly traced to any of the above four centres of infection, the following are the most important:—Southampton, where the deaths from small-pox increased from 24 in the first quarter of the year to 229 in the quarter ending June; Weymouth, where from two in the first they rose to 39 in the second quarter; Falmouth, which showed an increase from 11 to 27; Bridgewater, which showed 12 deaths last quarter; Oswestry, in which 14 deaths occurred last quarter; Stoke-upon-Trent, in which district 103 occurred in the second quarter, against but one in the first quarter; Nuneaton, in which the numbers were respectively 9 and 26; Coventry, which showed 4 and 14; and Great Grimsby, in which the deaths rose from 18 in the first quarter to 164 in the three months ending June last. The three Ridings of Yorkshire, comprising the ninth registration division, with its more than two and three-quarters millions of population, has hitherto comparatively escaped the effects of the

present small-pox epidemic; in the first quarter of this year the deaths from this disease in Yorkshire were but 69, while in the three months now under notice they had only increased to 98; of these, 21 occurred in Bentham and 20 in Kirk Leatham sub-districts, the former in the West and the latter in the North Riding.

In order the better to compare the degree of fatality from small-pox in various parts of the country, it is necessary to take the several populations into account. In the first quarter of this year the annual death-rate from this disease was equal to 9 per 1,000 in the whole of England and Wales; in the three months ending June it rose to 14 per 1,000. During last quarter the death-rate from small-pox was 4.0 in the London division, 1.5 in the Lancashire, 4.3 in Durham, and 2.9 in Northumberland. The annual death-rate from small-pox during the thirteen weeks ending July 1 in the different parts of London, after the distribution of the deaths in hospital, was 2 per 1,000 in the west group of districts, 3 in the central, 4 in the east, and 5 each in the north and south of London. The death-rates in a few of the larger boroughs which suffered more severely were as follows:—Liverpool 6, Newcastle-upon-Tyne 7, and Sunderland 9 per 1,000 persons living. In the following registration sub-districts the death-rates from small-pox were:—Southampton 19, Weymouth 11, Falmouth 8, Longton (Stoke-upon-Trent) 16, Nuneaton 8, and Great Grimsby 22. It is almost needless to add in conclusion of this short summary of the recent mortality from small-pox that in nearly all those places which have suffered most severely from the present epidemic great neglect of vaccination is reported; the omission, however, of the medical profession to state on the certificate of the cause of death the fact of vaccination or otherwise, renders it extremely difficult to obtain reliable statistics showing the proportion of fatal cases of small-pox in which vaccination had been entirely neglected or had been inefficiently performed.

### Sanitary Condition of Liverpool.

PROFESSOR PARKE and Dr. Sanderson who were appointed by the President of the British Association, at the instance of the Corporation of Liverpool, to report upon certain matters connected with the sanitary condition of that town, have transmitted to the Liverpool Council their report. They recommend the Council to seek powers to effect a displacement of the population and to facilitate the means of transport into the suburbs. Overcrowding in certain localities is the great evil with which the Commissioners are struck. The population in Liverpool they set down at 99.3 per acre, against 41.2 in London. The opening up of new and commodious streets they suggest as a first step, reserving the liberated spaces for approved labourers' dwellings and excluding the erection of stores or high houses. As sickness is the most expensive of all things, the Commissioners believe that the proposed measures would be remunerative in an economic point of view. They say, however, that the degradation and the disease disseminated by drunkenness is the great social sore, and they urge a combination of the employers of labour to control the conduct of their *employés*.

### How to Cure Sunstroke.

ON one of the very hot days there were recently, says the *Indian Public Opinion*, no fewer than nine men struck down by sunstroke in the Lahore Central Gaol. They were all quite insensible, and only able to breathe in that thick stertorous way peculiar to the ailment. The superintendent, Dr. Lethbridge, had them laid out in a row on the cool floor of the hospital, and there watered them copiously and continuously for five hours by means

of bheesties with mussucks, before much improvement was perceptible. Every man recovered, and it is to be noted as a circumstance of considerable importance that although all the cases were of the most serious kind, the simple remedy of a continuous and long continued supply of cool water was at last efficient. The remedy, continued only for half an hour, and perhaps interrupted every time the mussuck was empty, would evidently have been of no avail. We recommend the account to the attention of all travellers, and, indeed, of every one liable to be exposed to the heat of the sun.

In the August number of *The Doctor* there is an account of a discussion at Louisville College of Physicians, from which it appears that similar treatment has been successful in the Northern States of America, and that cold water largely drunk and freely applied to the spine is the best preventive of sunstroke.

### Over-crowding in Large Towns.

IN the report of the health of Liverpool just presented by Drs. Sanderson and Parkes a tracing was given showing the arrangement of streets where 4,748 people were crowded into a space which did not exceed 23,500 square yards; or, the compression of the population nearly equalled 1,000 persons to an acre. Within the courts each house was usually found to consist of a room on the ground floor, a room above this, and a third room in the attic. Most of them have cellars. It happens very frequently that there is a family in each room except the cellar. In many cases the staircase forms part of the rooms, and is without any window, so that there is an inevitable mixture of the air contained in all the rooms. Few constructions could be better adapted for the spread of contagious diseases.

IT is denied in a letter to the *Standard* that dyers use the aniline dyes, but a country doctor, in the same paper, offers to send to the incredulous traders specimens that have produced ill effects on some of his patients.

DR. HARDWICKE last week held an inquest on a little girl who had died in University College Hospital of hydrophobia. The child had been bitten by a dog that attacked her in the street, and has not yet been discovered by the police.

THE Army Competitive Examination was opened on Wednesday last at the London University. There were thirty-five candidates, and, we are told, only twelve or thirteen vacancies. Of the thirty-five competitors twelve were English, twenty-one Irish, and only two Scotch.

WE regret to announce the decease of Mr. Charles Aspray of Newton Road, Westbourne Grove, who died on the 2nd August, deeply lamented by all who had the privilege of knowing him. He had for some years retired from practice. All who knew him found in him a genial and intellectual companion.

THE Introductory Lectures to the Winter Session at the Metropolitan Medical Schools will be delivered, so far as announced, by Professor Rutherford, M.D., at King's College; Dr. T. H. Green, at Charing Cross Hospital; Mr. Le Gros Clark, at St. Thomas's; Dr. Alfred Meadows, at St. Mary's; Dr. W. T. Little, at the London; and by Mr. Bernard Brodhurst, at St. George's.

## Hospital Reports.

### KING'S COLLEGE HOSPITAL.

WEDNESDAY, JULY 13.

#### *Talipes Valgus.*

(Under the care of Professor Wood, F.R.S.)

THE first case brought into the operating theatre was one of talipes valgus, but, as Professor Wood observed, not the form commonly seen, where you have weakening and paralysis of the tibialis posticus as well as the ligaments on the inner side, and the foot turned inwards, but that rarer variety where the tendons of the peronei muscles were contracted, and you had eversion of the foot. Professor Wood first divided the peroneus tertius, then the peroneus brevis, and, finally, the tendon of the peroneus longus. The effect of these subcutaneous divisions were manifest, as the foot at once turned inwards. The Professor drew attention to the circumstance that he divided the tendons of the peronei at different sites, and for this reason, viz., that as the tendons lie in the same sheath, if they were divided at the same spot they would become united, and their individual action interfered with. Chloroform, he observed, was of value in these cases as a means of diagnosis. Immediately a patient was under its influence the contractions subsided, and *vice versa*. In talipes there was no actual shortening, it was a state of tonic tension, which subsided if the spasm of the nerve ceased. The plastic matter thrown out from the divided ends of the tendons is a soft material—colloid substance—like melted glass. The tendency of the new tissue was to contract, so that the limb was restored to its natural length; in extreme cases, however, elongation remained. Great care should be observed in the after-treatment of all such cases.

SATURDAY, JULY 15.

#### *Excision of the Elbow.*

(Under the care of H. SMITH, Esq.)

#### *Resection of Bones after Excision of Elbow.*

(Under the care of Sir WM. FERGUSSON, Bart., F.R.S.)

Mr. Smith, in the first instance, drew the attention of the class to the history of the case and the circumstances which led him to advise such a procedure. The patient had disease of the right elbow some years ago, resulting in osseous ankylosis. Her business was that of a cook, and this occupation she was unable to follow in consequence of the little use she had of the arm. She was unable, in fact, to raise the right hand more than within six or seven inches of her mouth. Being unable to follow her occupation—it being the right arm—and from previous operations he had performed of a similar character, both in the knee and elbow, were the reasons that led him to advise the operation, with a view to obtain a moveable and useful limb.

As soon as the patient was completely anaesthetised Mr. Smith made a longitudinal incision across the elbow, laying fairly bare the joint. He then very carefully proceeded to dissect, as far as necessary, on the radial side, and then by a series of cautious manoeuvres on the ulnar side, to expose fully the osseous structures, the assistant holding back with the blunt retractor the ulnar nerve. Mr. Smith then resected the bones, a wedge-shaped piece being sawn out. Three arteries were then taken up and tied, the edges of the wound brought together, and water dressing and a rectangular splint applied.

Mr. Smith, in commenting upon the case, said:—This operation was another advance in conservative surgery; formerly, no matter what position a joint was in, if *anchylosed* it was regarded as a cure, whereas now it was believed, and indeed shown to be possible, that a limb in the con-

dition of the one they had just seen could be so far restored, by allowing a false joint to form, as to be both useful and mobile. With reference to the operation itself, Mr. Smith regarded it as one of some difficulty, and requiring great care and caution in the various steps. It was much more difficult than a similar operation in the knee, and the result was dissimilar, because in the arm you hoped to obtain a *moveable joint*, but in the knee an *anchylosed joint* in a better position was all you could expect.

Sir Wm. Fergusson, prior to operating, stated that the young woman, who was strumous, had been operated upon some months ago for gelatiniform disease of the elbow-joint; since then her condition had much improved, but the disease had returned. Sir William then proceeded to lay the joint open, and by cutting, clipping, and with his fingers removed the diseased parts. He then sawed off a thin slice of the humerus and radius. The edges of the wound were brought together by one stitch only, water dressing and a rectangular splint were applied. Sir William then stated that the case Mr. Smith had operated upon and his own were of remarkable interest, illustrating, as they did, an advance in conservative surgery, which might be termed "progressive surgery." Some years ago such a thing as resection of the ends and removal of diseased tissue after excision of the joint had been performed would have been considered as unlikely to be of any use whatever. Now, Sir William could assure the class that not only might a second operation or resection be performed with advantage to the patient, but a third and even a fourth might be beneficial.

In the present case there were still one or two gelatiniform-like places, but he had no doubt that if the general health and condition of the patient improved that they would not give rise to any inconvenience, and possibly even assume a healthy character.

In conclusion, Sir William hoped the class would watch these cases; they illustrated an advance in conservative surgery of a peculiarly interesting character, and Sir William himself, from being the first to bring such operations forward, together with the success he had already obtained, led him to anticipate hereafter very favourable results in this field of "progressive surgery."

## HOMŒOPATHY—ITS PRINCIPLES EXPLAINED.

(Continued from page 125).

### LECTURE III.

DR. EPPS commences his third lecture by stating that Hahnemann arrived at his doctrine by "pure practical experience." We have before examined this point. He takes great pains to show that we ought not to deny the existence of the ten-millionth part of a grain; but it is not the existence so much as the medicinal efficiency of such quantities, that we do not recognise. Who will believe that an infinitesimal dose is capable of producing the effects Dr. Epps ascribes to it? "In the French edition of Hahnemann's *Materia Medica*, no less than forty-five octavo pages are devoted to the statement of 920 symptoms produced by the one-millionth of a grain of vegetable charcoal, and of 190 symptoms caused by the like quantity of animal charcoal." Among the many effects ascribed to these agents, we find "itching of the internal angle of the left eye," "itching in a wart on the finger," "repugnance for butter," "obstruction of the left nostril for an hour," "speedy loss of appetite by eating," &c., &c., &c. Dr. Epps's line of argument then is, that because things in general act in minute quantities, remedial agents do so; but we must remember that such a statement requires the proof of experience. The chemist knows how far he can proceed with the division of his agents, and what effects will follow. The physician knows from long ages of experience what effect will follow

the administration of a certain drug, and it will require great proof, rather than a surmise of probability, to justify him in reducing the usual dose to a degree that has astonished chemists, and, according to many, has actually exceeded the atomic division of the body. But, no doubt, homœopaths are advocates for the "infinite divisibility of matter." Further, Dr. Epps declares that "chemical action is favoured by separating the particles of which bodies are composed, hence the old chemical axiom, *corpora non agunt nisi soluta*, bodies do not act unless dissolved, in other words, when a body is dissolved, that is, when its particles are separated to the degree of fineness and minuteness as to be no longer visible, actions take place which do not when the body is of less degree of minuteness." Such is the statement, a statement, we believe, every tyro in chemistry would laugh at. To say that when a body is dissolved its particles are separated is, to a certain extent, true, but not all the truth. The fluid state favours action because of its mobility. Two lumps of a solid may be put together, but usually they will not show chemical action. Dissolve them, that is, not separate the particles, but put them in such a condition that they will get nearer to each other, and they will "act." As a proof that separating the particles destroys action, if we bring the two bodies into a gaseous state (in which the separation is more than the liquid) they will then be unable to unite. They cannot act in the solid state because the particles have not mobility, nor in the gaseous because they are too far separated. This is the almost universal theory of the best chemists. But then, if it were as Dr. Epps supposes, the facts would merely furnish a presumption of the possibility of the doctrine of "infinitesimal" doses being correct. Perhaps, however, it is allowable to stay in our direct enquiry to correct an error in natural science, although we are far more anxious than our opponent seems to be to arrive at the pith of his subject. We are first, however, treated to a history of the manufacture of homœopathic remedies, for which, as it does not touch the argument, we can scarcely find space. We may, however, give the strength in his own words:—"In this way the solutions are carried to the decillionth part of a grain. When these solutions are to be brought into use, it is the custom to moisten with them little globules of sugar; these absorb the liquor and become impregnated therewith. These globules, thus impregnated, are those sold in homœopathic medicine chests." This will enable our readers to form an idea of the doses employed, and to calculate how far an insoluble substance, after being rubbed with milk-sugar for some hours, is rendered soluble. Suppose the decillionth part of a grain of charcoal or steel be put into two hundred drops of a liquid, it is diffused through the whole? Certainly not. It is insoluble, and so will occupy but the fraction of one of those drops. But any one of those drops will moisten about twenty of their sugar balls, and are made to do so, and we are gravely told that each of these globules contains the dose. How much greater must the improbability of its being in any single globule be, when the dilutions of the liquid have been extended! In every instance of an insoluble substance used this must be the case, and may be shown by going through the process with visible quantities. Can there be a thousandth part of the globules medicated? Dr. Epps says, "If chemical action takes place powerfully, when bodies are thus extended, may we not infer that the medicinal action of these, thus extended medicines, may be correspondingly powerfully effective." But this is a false position. Chemical action does not take place more powerfully for this extension (or dilution). It is weakened, and in the same way we suppose the effects of drugs to be weakened in proportion as we diminish the dose, and this is a well-established fact. Every one, or almost every one, has taken a dose of castor oil, and is quite aware that if he does not desire so violent an effect, he must take a less quantity. Chemistry furnishes thousands of illustrations all proving the less the quantity the less the effect. Take

for instance the explosion of gunpowder. A quarter of an ounce will carry a considerable distance by its power, but if we reduce the quantity to a grain its effect is a mere nothing, and, to treat it homœopathically, we should find no effect from it. How then can he urge that his practice is founded on things in general "acting in infinitesimal quantities." Again, an acid colours test paper, but dilute the acid and you weaken the colour, and you may go on diluting till it will fade altogether. It is not true then that chemical actions take place more powerfully thus extended, nor does it seem to be true of medicinal actions.

He then digresses into his old argument that we cannot see particles which exist. The particles that smell, for instance, or that cause a disease. Well, we can only tell him, that if we cannot tell him the "size" of one of these particles he cannot tell us the number required for any effects. It is useless to repeat every one of these illustrations, or endeavour to correct an error in science that our opponent has committed. Suffice it to say that by passing them over we do not commit ourselves to the doctor's theories. But we are to remember, says Dr. Epps, if these doses are small "in disease, there is an augmented susceptibility to impression; so that what in health or in another state would have no effect, will have and does have a most powerful effect in this state of increased susceptibility." Is this true? Is this the general rule? We believe not. It may sometimes happen that an individual cannot take so much as usual of a drug without too violent effects; but is it not far more common (or at any rate very common) that more is required than in health? Do we not all remember taking pills when one will suffice usually? Have not enormous, even poisonous doses of laudanum been given with impunity to delirious patients? Have not such quantities of brandy and wine as would disturb Dr. Epps' stomach and brain been taken by many with advantage who must have died without it? Is it not a common and true remark, that "many have been saved by pouring poison down their throats?" The homœopathic practice is then evidently not defended by the fact of any "increased receptibility of the system." Dr. Epps says, if those people who "foolishly assert they would take a whole chest of homœopathic globules, would take the same medicines in doses proportioned to the receptibility of the system in health, they would soon find the truth of Hahnemann's observations." Can Dr. Epps give us any rule for calculating its "receptibility in health?" We may then make our observations with more certainty; accuracy will then be evident in our investigations. We know several people who have frequently experimented on themselves and friends, but they have all uniformly found that they must take a dose very far from homœopathic in order to produce any effect. If Dr. Epps will name the homœopathic dose to be used in health, we can find plenty who will willingly try its effect.

Dr. Epps thus concludes this lecture:—"But if any one still doubts the efficacy of these infinitesimally small doses in curing diseases" (doubtless there are many who do doubt), "let me ask what are the dimensions of the particles which induce diseases in people previously well?" We need not stop to inquire whether Dr. Epps adopts the hypothesis of insect-life as the cause of disease, or of some peculiar virus acting through the medium of the atmosphere. It is a matter of little consequence. If it is no modification of vital force or any such subtle cause that produces disease, at least in contagious diseases it would be difficult to find an answer to the question—"How numerous are these particles you speak of?" A patient is seized with small-pox or malignant fever, and Dr. Epps asks the "size" of the particles that cause it. What is the number? It must be many for he can impart the disease to a whole house, street, or even city, and yet it has not cured him. If there were only one particle, on giving it to another person he would be well; but this is not the case. Dr. Epps gives several illustrations—"influenza," "small-pox," "cholera," &c.; but the same answer applies

to all. If not too much for the reader, we will remark that the most probable explanation of many of the diseases is that the particles are introduced into the system, and during what is called "the period of incubation," multiply and increase till the effect begins to be seen. Of course this will only explain certain classes of disease; others may be an increase of vital power, others a decrease, &c. These are some few reasons for not believing the homœopathic doctrine to be founded in science. There is nothing else that is analogous to it except in the brains of a few men, who pretend neither to strict science nor true philosophy. We do not, as Dr. Epps asks, object to homœopathic doses because we cannot see them, or as he tells us we might object to the existence of musk on a man's coat, though we could smell it strongly. That would be the evidence of one sense at any rate! But the effects of these doses are not appreciable by any sense or philosophy. Although we may doubt their existence, that is not the main question. What we say is that, if they do exist, they are not efficacious. Yes, the effects! the effects!! that is the question! and, though the present chapter is professedly devoted to the subject, we can see nothing which proves it reasonable, or shows that it has any effects. We hope our readers patience is not quite exhausted, as we have a few remarks on his fourth lecture.

#### THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE twenty-sixth annual general meeting of this Association was held on the 3rd inst., at the Royal College of Physicians, London, when Dr. Maudsley, president, delivered an address. He considered three points—1, the prevention of insanity; 2, the treatment of the insane in private houses and asylums; and, 3, the use and abuse of sedatives in the treatment of insanity.

The question of the prevention of insanity, although a most important one, had hardly ever been seriously propounded. Luckily for us, insanity, unlike some other fearful diseases, could not be conveyed by man to his fellow-man by infection or contagion; but, on the other hand, it was of all diseases the one most likely perhaps to be inherited by one generation from that preceding it. Then, again, it was a disease of so fearful a nature, affecting the highest and most distinctive of man's attributes—mind—that the sufferer from it was regarded as having really sustained a fall from man's high estate, and his relatives accordingly often strove their hardest to conceal the fact. If we had certain animals who were deficient in what ought to be their chief characteristics—greyhounds, for instance who could not run fast, or race-horses who were deficient in speed and staying power, should we make choice of these for the purpose of propagation? Certainly not. Then the question arose, ought we to permit men in whom there was a tendency towards mental alienation to marry? This was a most difficult question by reason of the different degrees of liability to insanity which necessarily existed in different individuals. Then, again, the phenomena of atavism and the alternation of neuroses very much complicated the question. For instance, the son of a madman may escape and the grandson be utterly insane; and the off-spring of epileptic or neuralgic parents may show very strong tendencies towards insanity. Again, it had been remarked that the offspring of the insane had not unfrequently been men of great genius, and hence the question arose whether, by forbidding the marriage of a man with tendencies towards insanity, we might not be depriving the world of a mind which would more than compensate for innumerable mental aliens. The descendants of the insane are often very original thinkers. They explore the little-trodden paths of knowledge, they have often indomitable energy, and are careless of all obstacles. Dr. Maudsley thought that if a man had actually had an attack of insanity, we ought to use all our powers of persuasion to prevent his marrying, but in other cases he did not recognise the utility of interfering. He thought that not much had to be done for the prevention of insanity by the prohibition of marriage, but that more could be done by the careful and scientific education of the children of the insane. No person predisposed towards insanity should be considered as a helpless victim to his fate. A man can, to a certain extent, by sheer force of his will, make his character

grow to the ideal he sets before himself, and, undoubtedly, a great deal is to be done by the careful mental training of those predisposed towards insanity. The insane themselves, it is well known, have at times a great power of control over their actions; and, *à fortiori*, those who are merely predisposed towards insanity should be likewise able to exercise this control. Unfortunately, as a rule, children with an hereditary taint are always worse managed than other children, and are, therefore doubly cursed.

With regard to the treatment of insane persons, Dr. Maudsley thought that the fashion of at once dispatching a lunatic to an asylum should by no means be necessarily followed in all cases. Many cases recovered without ever being sent to an asylum, and many cases were on record which baffled all treatment while resident in an asylum, but rapidly recovered after effecting their escape. M. Comte was a notable instance of this. He was an inmate of Esquirol's asylum, but, managing to effect his escape, he recovered and wrote his famous work on "Positive Philosophy." On the whole, Dr. Maudsley thought that only in a very few cases was it absolutely necessary to send the patient to an asylum. The recovery of many patients was retarded by the absence of "home influence," and the utter banishment from their friends and relatives which was entailed upon them. It was unfortunate that the treatment of the insane had become such a narrow speciality, and it would be an excellent thing if the state would authorize medical men to receive a very small number, say two or three, insane patients into their houses. He believed that patients placed in this position would be more likely to do well than those who were sent to larger establishments.

Disputing the use and abuse of sedatives, Dr. Maudsley doubted if it were always a wise thing to stifle excitement, and whether a chemical restraint put upon the brain-cells was not often as injurious to the patient as a mechanical restraint imposed upon his limbs. He thought that sedatives were given far too recklessly; that, although they might relieve symptoms, they often only served to push the patient further down the hill, and, as often as not, retarded recovery. He thought the whole range of sedatives, including bromide of potassium and the hydrate of chloral, were all equally capable of being abused; that by giving them we often materially damage the patient's general health, and, instead of curing, we often merely "made a solitude, and called it peace."

#### Literature.

##### DYNAMICS OF NERVE AND MUSCLE.\*

DR. RADCLIFFE has long held rather peculiar doctrines. His position entitles him to a hearing, and we may add, the conscientious work he has done, should excuse even those who differ from him to give him full scope. We are not prepared to endorse his views, and just now we have not space to attempt to refute them. We, therefore, beg to report that the present work may be looked upon to some extent as a new edition of a former volume. It presents the author's most recent researches and conclusions on a most interesting subject. We will give him space to tell in his own words what he maintains, and thus we cannot be said not to do justice to him. He thus sums up his views:—

"Instead of regarding the state of action in nerve and muscle as a manifestation of vitality, there is, indeed, reason to believe that it must be brought under the dominion of physical law in order to be intelligible, and that a different meaning, also based upon pure physics, must be attached to the state of rest.

"There is reason to believe that all kinds of electricity act upon nerve and muscle by way of charge and discharge, the charge antagonizing, the discharge permitting, the state of action.

"There is reason to believe that the blood acts upon nerve and muscle, not by causing the state of action, but by antagonizing it.

\* "Dynamics of Nerve and Muscle." By Charles Bland Radcliffe. London: Macmillan & Co. 1871.

"There is reason to believe that 'nervous influences' act upon nerve and muscle, not by causing the state of action, but by antagonizing it.

"The whole case is simple enough. It would seem, indeed:—

"(1) That the sheaths of the fibres in nerve and muscle are capable of being charged like Leyden jars, and that during the state of rest they are so charged.

"(2) That the sheaths of the fibres in muscle are highly elastic.

"(3) That the fibres of muscle are elongated during the state of rest by the charge with which their sheaths are charged, the mutual attraction of the two opposite electricities disposed, Leyden-jar-wise, upon two surfaces of the sheaths, compressing the elastic substance of the sheaths and so causing elongation of the fibre in proportion to the amount of the charge.

"(4) That the muscular fibres contract when the state of rest changes for that of action, because the charge which causes the state of elongation during rest is then discharged, and because this discharge leaves the fibres free to return, by virtue of their elasticity simply, from the state of elongation in which they had been previously kept by the charge, and the degree of contraction is proportional to the degree of elongation previously existing.

"(5) That the fibres of nerve are not affected in the same way as the fibres of muscle by the charge and discharge of electricity, because the sheaths of the fibres may be wanting in the requisite degree of elasticity.

"(6) That the blood antagonizes the state of action in nerve and muscle by helping to keep up the natural electrical charge which antagonizes action.

"(7) That 'nervous influence' antagonizes the state of action in nerve and muscle by helping to keep up the natural electrical charge which antagonizes action.

"(8) That diminished efflux of blood to certain nerve-centres leads to successive action in nerve and muscle by disturbing the electric equilibrium of the nervous system which is maintained during the state of rest, this disturbance causing a partial reversal in the relative position of the two electricities with which the sheaths of the fibres are charged, and so necessitating the discharge which is the basis of the state of action; for by this partial reversal, sheaths of which the charge has become negative at the sides and positive at the ends are brought into juxtaposition with sheaths, of which the charge remains positive at the sides and negative at the ends—are brought into a relation which necessitates discharge, for discharge must happen when opposite electricities come together."

## Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I request you will have the goodness to publish the following case which, though not containing anything very remarkable as far as the operation is concerned, was followed by a circumstance in the course of the after-treatment, which is both interesting and instructive.

Yours truly,

H. THOMPSON, M.D.

Omagh, August 5th, 1871.

### REMOVAL OF TUMOUR FROM BACK OF NECK.

—Cullen, *et. seventy-one*, admitted into the Tyrone Infirmary on the 10th July, 1871, praying to be relieved of the insufferable annoyance caused by a tumour very nearly as large as his head, which hung from the nape of his neck. It was quite loose and moveable over the subjacent parts and under the skin. His general appearance indicated pretty fair health, and he exhibited no symptom of any visceral disease. The operation was accordingly performed by a vertical elliptic incision in the mesial line, including a breadth of integument of about three inches; the dissection occupied about two minutes, and was performed without the aid of chloroform, as it was found to produce irregularity in the action of the heart. Three vessels required ligature, the wound was brought together by three points of suture with adhesive straps between, and dressed by means of a dry compressed bandage.

Third day.—Wound united in entire extent by first intention. Suffers no uneasiness whatever; removed the sutures.

Tenth day.—Ligatures all away, cicatrix linear, union complete; feels weak and giddy when he sits up; complains of want of appetite; pulse feeble and intermittent; ordered brandy two glasses daily.

Eleventh day.—Debility increased; extremities cold; pulse very feeble and fluttering; mind wandering; ordered at once a full glass of brandy, and half a glass every second hour.

Twelfth day.—Strength improved; expresses himself as having derived great benefit from the brandy, of which he has consumed six glasses since yesterday.

Fifteenth day.—An erysipelatous blush has appeared on right side of face engaging lower eyelid, which is swollen; no appearance of the kind above wound; continue brandy.

Seventeenth day.—Erysipelas progresses, engaging nose. He is greatly relieved since this made its appearance; continue brandy.

Twenty-first day.—The attack has come to an end, after having engaged the nose and opposite side of face from all the parts affected, the cuticle is now desquamated. He has quite recovered his strength and is able to walk about. The brandy has been discontinued, two glasses of wine daily being found sufficient.

Twenty-fourth day.—Discharged cured. The remarkable circumstances connected with this case is the extreme collapse and depression which preceded the attack of erysipelas, the subsequent mildness of that disease when it appeared, and the relief its appearance occasioned. Had brandy *ad libitum* not been administered during the stage of the incubation, the man would have died, before the cutaneous inflammation had shown itself, and the death would have been attributed to the nervous shock sustained in the operation.

The tumour after removal was found to weigh two pounds and three quarters. It had the appearance of fat contained in cells of a dense and heavy fibrous structure, and surrounded by a distinct fibrous cyst or envelope.

### DR. INGLIS ON THE USE OF THE LONG FORCEPS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a subscriber of your Journal, may I ask the favour of your inserting in it the following, and your full opinion on it. In the MEDICAL PRESS, of the 21st June last, Dr. A. Inglis has a paper headed, "On Using Long Forceps, Introduction of Blades in Occipito-anterior Presentations." "The occiput having been ascertained to be near the right groin, &c. &c." "After this the left half of the forceps is introduced" (I would wish to know which he calls the left half—is it the upper or lower blade?) and when finally adjusted lies immediately in front of the transverse bisection of the pelvis at the brim, with its tip resting behind the left ear." "The second blade is next introduced, &c." "It is then rotated partially by supination (ought it not to be pronation) of the right hand? &c." "This second blade will be in the posterior half of the right side (according to this are not both blades in the same side—the right—which would be impossible) of the pelvis at the brim opposite the sacro-iliac, (what sacro-iliac?) joint, and should cover the right zygomatic region of the head."

Now, is not Dr. Inglis speaking all the time of the head in the second position; for according to Dr. Tyler Smith's excellent "Manual of Obstetrics," the occiput is in the second position turned towards the right acetabulum, and the forehead towards the left sacro-iliac synchondrosis, &c. The left ear is felt behind the pubis. If so, both doctors agree, but in the same paper further on, Dr. Inglis says—"In the second position of the head, the introduction is exactly similar in all respects?"

Really, I cannot reconcile these, to me, quite opposite statements of Dr. Inglis, for he evidently begins with the second position, and then having done with it, he begins to speak of the second position as another. Can it be that he means the first position as the one he begins with. To my mind it cannot, for then it is the right ear behind which the first blade of the forceps would rest, according to Dr. T. Smith, and not the left, and the occiput would be towards the left acetabulum.

The brackets and underlinings are mine.

I have not seen the MEDICAL PRESS of the 8th June, 1870, to which Dr. Inglis refers.

Yours, &c., &c.,

August 2nd, 1871.

STUDENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—You are at liberty to publish the enclosed prescription sent to London to be made up for a consumptive patient, who is under treatment by the author of the prescription, a clergyman in the West of England, reputed of great skill in diseases of the chest.

Yours truly,  
M.D.

P. S.—As the College of Physicians have just made a number of young Fellows, and left out in the cold far too many deserving members, might it not be justice to propose the clerical for fellowship at once.

FOR CONSUMPTION.

1 oz. isinglass ;  
1 oz. Eringo root ;  
half pint garden snails ;  
half oz. Hartshorn shavings ;  
3 dried vipers from Butler's, Covent Garden ;  
One and a-half pints of water to be reduced to a pint.

## Medical News.

**Royal College of Physicians of London.**—At an extraordinary meeting of the College on Monday, the 7th inst., the following Members were admitted fellows :—

Child, Gilbert William, M.D., Oxford.  
Copeman, Edward, Upper King st., Norwich.  
Drake, Augustus, M.B., Southerhay, Exeter.  
Fox, Tibury, M.D., 43 Sackville st.  
Hensley, Philip John, M.D., 4 Henrietta st., Cavendish sq.  
Hitchman, John, M.D., Mickleover, near Derby.  
Leared, Arthur, M.D., 12 Old Burlington st.  
Stevenson, Thomas, M.D., Guy's Hospital.  
Williams, Chas. Theodore, M.D., 78 Park st., Grosvenor sq.

And the following gentleman was admitted a Licentiate of the College :—

Noad, Henry Carden, George's Hospital, S.W.

**University of London.**—The following is a List of the Candidates who have passed the recent First M.B. Examination :—

### FIRST DIVISION.

Branfort, Henry Seymour, Guy's Hospital.  
Buchanan, Arthur, Guy's Hospital.  
Colgate, Henry, University College.  
Dodson, Andrew, Queen's College, Birmingham.  
Firth, Charles, St. Bartholomew's Hospital.  
Rayne, Charles Alfred, University College.  
Schaff, Edward Albert, University College.  
Skerritt, Edward Markham, B.A., University College.  
Smith, George Francis Kirby, Guy's Hospital.

### SECOND DIVISION.

Addy, Boughton, St. Thomas's Hospital.  
Appleyard, John, University College.  
Ashby, Henry, Guy's Hospital.  
Barber, Edward Creswell, St. George's Hospital.  
Blake, Samuel Hahnemann, University College.  
Boddy, Hugh Walter, Manchester Roy. Sch. of Med.  
Burn, George Wilson, St. Bartholomew's Hospital.  
Crespin, E. R. L., Guy's Hospital.  
Dyson, William, B.A., University College.  
Harvey, Charles William, University College.  
Kennedy, Edward, B.A., Manchester Roy. Sch. of Med.  
Knox, David Neilson, M.A. Glasg., University of Glasgow.  
Lees, David Bridge, University of Cambridge.  
Lewtas, John, Liverpool School of Medicine.  
Parry, Thomas Sharpe, University College.  
Sturge, William Allen, Bristol Med. Sch. and Univ. Coll.

### EXCLUDING PHYSIOLOGY.—SECOND DIVISION.

Dundas, George Albert, Guy's Hospital.  
Hickman, Richard, St. Mary's Hospital.  
Nicholson, Arthur, King's College.

### PHYSIOLOGY ONLY.—FIRST DIVISION.

Branfoot, Arthur Mudge, Guy's Hospital.

### SECOND DIVISION.

Davies, David Arthur, University College.  
Moss, Herbert Campbell, King's College.  
Owen, Edmund Blackett, St. Mary's Hospital.  
Summerhayes, William, St. Thomas's Hospital.  
Taylor, John (B), Guy's Hospital.  
Williams, William, Guy's Hospital.

**British Ales.**—At the Naples Exhibition Mr. Younger carries off the First Prize Medal for superior excellence of his India Pale and Edinburgh Ales.

**University of Edinburgh.**—The following is a list of candidates who received degrees in Medicine and Surgery on Aug. 1st :—

### DOCTOR OF MEDICINE.

Brown, Joseph, Scotland, M.B. and C.M. 1866.  
Buist, John Brown, Scotland M.B. 1867, C.M. 1870.  
Burman, James Wilkie, England, M.B. 1868.  
Christie, James, Scotland, M.B. and C.M. 1868.  
\*Cumming, James, Scotland, M.B. and C.M. 1868.  
Dalton, Henry, Demerara, M.B. and C.M. 1868.  
Duncanson, John Janet Kirk, Scotland, M.B. and C.M. 1869.  
Foss, Robert William, England, M.B. and C.M., 1868.  
Glascott, Charles Edward, England, M.B. and C.M. 1868.  
Hett, Geoff'ey, England, M.B. 1867.  
Heycock, Francis Saworth, England, M.B. and C.M. 1868.  
†Hunter, John, Michell, England.  
‡Joynnt, Francis George, Ireland.  
Law, Alfred Roberts, England, M.B. and C.M. 1869.  
MacLaren, Robt. Philip, New Brunswick, M.B. and C.M. 1868.  
Munro, Robert, M.A., Scotland, M.B. and C.M. 1867.  
Oman, Nathaniel Daniel Isaac, Scotland, M.B. and C.M. 1865.  
\*Pritchard, Urban, England, M.B. and C.M. 1869.  
Roberts, David William, Wales, M.B. and C.M. 1869.  
Serra, Claudio Lisboa, Rio de Janeiro, M.B. and C.M. 1868.  
Syms, William Henry, England, M.B. and C.M. 1866.  
Walker, Archibald Dunbar, India, M.B. and C.M. 1868.  
Wright, Strehill Henry, Scotland, M.B. and C.M. 1867.

\* Obtained prizes for their dissertations—gold medals.

† Under the old statutes.

### BACHELOR OF MEDICINE AND MASTER IN SURGERY.

**Guy's Hospital Medalists and Prizemen, 1870-71.**—The Treasurer's Gold Medal for Medicine : G. Davidson Deeping. The Treasurer's Gold Medal for Surgery : Henry Edward Southee. Third-year's Students : C. H. Golding Bird, first prize, £40 ; George Turner, second prize, £35 ; Thomas Eastes and Edmund Arthur Burgess, honorary certificates. Second-year's Students : F. Akbar Mahomed, first prize, £35 ; George F. Mastermann, second prize, £30. First-year's Students : Arthur Henry Jones, first prize, £30 ; Charles Edward Barnard (Tasmania), second prize, £25 ; Henry Clarke and William Harry Hansard (equal), £10 10s. each ; Hugh Alex. Cookson, Thos. Simmons Morley, Robert Neale Smith, and Carlos Duran, honorary certificates.

**Apothecaries' Hall of London.**—At a Court of Examiners, held on the 10th inst., the following gentlemen, having passed the necessary examinations, were admitted Licentiates of the Society of Apothecaries, viz. :—

Garton, William, St. Helen's, Lancashire.  
Pearee, Joseph Channing, Manor House, Brixton.  
Wheeler, D. M. Brunwell, Chelmsford.

And at the same Court the following passed the primary professional examination, viz. :—

Hansell, W. C., Guy's Hospital.  
Kessen, A. E., Guy's Hospital.  
Le Mottée, G. H., King's College.  
Paul, F. T., Guy's Hospital.

Spark, S. W., Guy's Hospital.  
Whitmore, W. T., St. Bartholomew's Hospital.

The Director General presents his compliments to the Editor of "THE MEDICAL PRESS AND CIRCULAR," and begs to enclose for insertion a List of the Candidates of Her Majesty's British Medical Service who were successful at the competitive Examinations held at London, in February, and at Netley in August, 1871, after having passed through a course at the Army Medical School, Netley.—Army Medical Department, August 10th, 1871.

| NAMES.                | STUDIED AT                        | NUMBER OF MARKS. |

**Bequests to Medical Charities.**—The will of James Stewart Forbes, Esq., late of Chester House, Wimbledon, Surrey, was proved in London, on the 12th ult., under 60,000*l.* personalty. The will is dated in 1868, and testator died May 7 last. Upon the decease of his sister, he leaves the following charitable bequests—namely, to the Brompton Hospital for Consumption and the Diseases of the Chest, the Middlesex Hospital, London University College Hospital, St. Mary's Hospital, the Asylum for Idiots (Earlswood), each 5,000*l.*; and to the Hospital for Children, Great Ormond street, London, 1,000*l.*

NOTICES TO CORRESPONDENTS.

**TO OUR SUBSCRIBERS.**—Gentlemen who have not paid their subscription for last year are respectfully reminded of the omission. The Publishers would also be much pleased to receive arrears of subscriptions due for several years previously, which, in too many instances, remain unpaid, notwithstanding frequent applications for settlement.

**NOTICE.**—Subscribers are respectfully reminded that payment by P.O.O., or crossed cheque, is the most convenient and safest mode of remittance. Stamps are unfortunately too easily disposable by dishonest persons.

All valid receipts are given upon printed forms. Subscribers and advertisers are particularly cautioned against making any payments without the production of such a receipt. Cheques or P.O.O. should be made payable in England, to A. A. Tindall; in Ireland, to A. H. Jacob, M.D.; in Scotland, to MacLachlan and Stewart.

**MEDICUS.**—Declined, with thanks.

**DR. SMITH.**—The subject shall have our earliest consideration.

THE HEALTH OF SCARBOROUGH.

To the Editor of "The Medical Press and Circular."

SIR,—Having had several applications from distant friends, as to the existence of small-pox in Scarborough at present, a prevalent report having got into circulation to that effect at a distance. I am happy to assure you that, so far as my own observations have extended, and from the testimony of other Medical men, who visit almost every part

of the town daily, that the report is without any foundation whatever, and that Scarborough was never more healthy than at present.

I am, Sir, yours, &c.

THOS. T. PEIRSON, M.D.

Falsgrave, Aug. 12, 1871.

The following communications are in type, and will appear, if possible, in our next:—

W. E. Teevan, B.A., F.R.C.S., "Case of Retention of Urine from Impassable Stricture, treated by Filiform Bougies."

G. Smith Chartres, M.A., M.D., "Syphilitic Iritis attacking both Eyes in succession, treated principally by Oil of Turpentine and Blisters."

Dr. Francis M. Luther, "Case of Progressive Locomotor Ataxy."

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Two Pamphlets, by Robert H. Collyer, M.D., "On Anæsthetic History."

Chemical Tables for the Use of Students. By A. Collinette, M.R.C.S. Guernsey.

Animal Physiology. By E. D. Mapother, M.D. London: Longman and Co.

The American Journal of the Mental Sciences. British Journal of Dental Science. Science Gossip. The Practitioner. New York Medical Gazette. Boston Medical Journal. Le Mouvement Médical. Detroit Review of Medicine.

VACANCIES.

University of Durham. Medical Tutor. Salary £120 per annum.

Chester Infirmary. Visiting Surgeon. Salary £80 with board and residence.

Bradford Infirmary. Physician. Honorary.

Coventry Dispensary. Surgeon. Remuneration averages about £180.

Norwich Hospital. House-Surgeon. Salary £100, with board.

St. Giles and St. George's Parishes, London. Medical Officer. Salary £150 per annum, with residence and washing.

APPOINTMENTS.

ALLEN, M., Resident Accoucheur at St. Bartholomew's Hospital.

BARR, Dr. J. W., Resident Medical Officer to the Bury Dispensary.

BOURNE, M. W., M.D., Resident House-Surgeon and Apothecary to the Royal Orthopedic Hospital.

BURMAN, J. W., M.D., Assistant Medical Officer to the West Riding Lunatic Asylum.

CAYLEY, W., M.D., Physician to the London Fever Hospital.

COOKE, T., F.R.C.S.E., Assistant-Surgeon to the Westminster Hospital.

HILL, T. W., M.R.C.S., House-Surgeon to the West London Hospital.

MACRATH, J., Assistant Resident Medical Officer to the Leeds Dispensary.

MEADOWS, A., M.D., M.R.C.P., Lecturer on Midwifery and the Diseases of Women and Children at St. Mary's Hospital Medical College.

PEARSE, G. E. L., F.R.C.S.E., Surgeon to the Westminster Hospital.

POPE, H. C., House-Surgeon to the Seamen's Hospital, Greenwich.

POWELL, R. D., M.D., M.R.C.P.L., Lecturer on Materia Medica at the Charing-cross Hospital Medical College.

SPEEDING, Dr. B. H., Medical Officer to the Belfast Dispensary.

THORNTON, J. C., M.D., a Physician to the West London Hospital.

Births.

MARSHALL.—On the 1st inst., at High street, Chard, Somerset, the wife of T. Harrison Marshall, M.R.C.S. Eng., L.S.A., of a daughter.

Marriages.

MAUNSELL—FOSBERY.—On the 27th of April, at Hokitika, N.Z., Henry Widenham Maunsell, M.B., B.A., Surgeon-Superintendent of the Hokitika Hospital, to Mary Augusta, fifth daughter of Frank Fosbery, Esq., late of Curragh Bridge, co. Limerick, Ireland.

PALMER—BARBOR.—On the 8th inst., at the Parish Church, Cheltenham, T. W. Gascoigne, of Cheltenham, to Clara Harriette, daughter of Major George Alexander Barbor, late of the 8th Bengal Light Cavalry.

Deaths.

ASPRAY.—On the 2nd inst., Charles Aspray, Surgeon, of Newton road, Bayswater, aged 66.

BRADY.—On the 12th ult., at Geneva, Switzerland, Thos. Clark Brady, M.R.C.S., formerly Surgeon 1st Batt. 5th Regiment.

GREEN.—On the 3rd inst., Edwin Septimus Green, L.R.C.P. Edin., L.R.C.S. Edin., of Settle, Yorkshire, aged 27.

GRYLLE.—On the 1st of July, at Cononada, India, W. R. Grylle, M.D. Civil Surgeon.

GOWLAND.—On the 28th ult., John E. Gowland, M.D., M.R.C.P.L., of Great James street, Bedford-row, aged 41.

THORNLEY.—On the 5th inst., Robert Samuel Thornley, M.R.C.S.E., L.S.A. of Long-street, Devizes, aged 45.

WHITE.—On the 29<sup>h</sup> of June, at Perampore, Moorshedabad, suddenly, of cholera, John White, M.D., Surgeon-Major.

### CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE IX.

*Ovarian cystic disease—Pathology of—Unilocular, Multilocular, and Dermoid Varieties—Symptoms of—Diagnosis of.*

AS THE operation of ovariectomy has been twice performed in our wards within a comparatively recent period, one of the patients being still in hospital, I do not think it likely that I shall have a better opportunity than the present for drawing your attention to the subject of ovarian disease. The affections to which these organs are liable have till within the last few years, been looked upon as almost incurable, but now, as you are all aware, the extirpation of one, or both, of them when in a state of disease is performed with great frequency, and although its results are most uncertain, and though patients doubtless die from the effects of it, who might otherwise live for years, still the number of women whom the operation has restored to perfect health is so great that it will most probably hold its ground, or possibly even increase in public favour.

The affection to which I shall first direct your attention is that known as cystic disease of the ovary, by which term is understood the development of a cyst or sac, or of several cysts, within the ovary, which are filled with a fluid or semi-fluid substance produced in their interior. The development of cysts in the ovary is of very frequent

occurrence. They are met with of all size, from that of a pea to that of a large sac capable of containing many gallons of fluid. Pathologists now agree that the ovarian cyst is in the first instance the mere dilatation of a Graafian vesicle, this question having been virtually settled by the discovery by Rokitansky of an ovule within one of these diseased cysts. As the cyst grows all trace of its origin is lost, and the sac thus formed becoming distended with fluid gives origin to the simplest form of ovarian dropsy to which from there being but one cyst present, the term "unilocular" is applied. But very generally more than one cyst is developed, several of the Graafian vesicles becoming simultaneously affected. In the early stages we may have a cluster of small cysts, none of them perhaps larger than a currant; then after a time one or two of these seem to take on a condition of active life, and to become rapidly developed, swelling and increasing till they attain a large size, while the others remain stationary or increase slowly. To this aggregation of the cysts the term "multilocular" is applied; the multilocular tumour is much more frequently seen than the unilocular. The contents of these cysts vary in as great a degree as do their appearance. The unilocular generally contains a light, straw coloured fluid, very like serum in chemical qualities. Sometimes however it is turbid and ropy, and occasionally seems to contain blood. In the multilocular the contents of the cysts even in the same ovary vary much; in some they are similar to that just described; in others they consist of a thick gelatinous-looking mass, which is sometimes black and tenacious. Again, the walls of contiguous cysts containing fluids essentially different may be absorbed under the influence of pressure, and the contents becoming commingled we have then a fluid partly thick and tenacious partly aqueous. But in addition to this growth by the amalgamation of contiguous cysts, there is yet another and very important process by which these cysts increase, that is by the development within the parent cyst of numerous other cysts. These, according to Dr. Hodgkin, whose observations have been confirmed by Mr. Paget, may be either sessile or pedunculated, and may cluster in warty-looking masses on the inner surface of the sac. Thus by the growth of the older cyst and the rapid for-

mation of the new, the ovarian tumour sometimes enlarges with an alarming rapidity, and then the disease generally proves fatal in a very brief space of time. But ovarian tumours are seldom made up of these fluid-containing cysts alone. We nearly invariably find also a considerable amount of so-called solid matter present; this solid matter is produced at the same time as the cyst; sometimes it is small in quantity, sometimes in bulk it exceeds that of the fluid containing the cyst, and it may form a tumour of enormous magnitude.

These partly cystic, partly solid tumours to which the term "compound" is usually attached are probably the most common form of ovarian disease. In them solid matter exists under various forms, one which has been described by Mr. Spencer Wells as being identical in structure with the adenoid growths found in connection with the mammary gland has been called by him *Adenoma* of the ovary. Another remarkable one was long looked upon as malignant, a view now proved to be erroneous, it is termed *Alveolar*, and is likened by Dr. Farre to a sponge, the cells of which are filled with a jelly-like substance. Other varieties of solid material are also met with in these cases of compound ovarian tumours, but it would be impossible for me to enter with any degree of minuteness into these pathological details, for I desire in these lectures to confine myself as strictly as possible to the clinical aspect of the diseases of which I treat, and therefore must refer you to the writings of Paget and Farre, or to the admirable systematic works of Graily Hewitt, West, and others, for further information on the points which I feel compelled to omit.

There is however one other variety of ovarian cyst which I must notice briefly, namely, that which contains hair, plates of bone, fat, and in which even rudimentary teeth have been found, with or without any fluid being present. These tumours seldom attain any large size, and may remain indolent for years; on the other hand, they sometimes inflame, suppurate, and finally may cause death. These *dermoid* cysts, as they are termed, are a puzzle to pathologists; the fact that they sometimes are found in very young children negatives the idea of their being the product of conception, while equally it is difficult to admit, as some have suggested, that they may be the imperfect development of an ovum which has since been impregnated, but in truth this matter is as yet a complete mystery.

Having thus given you a brief outline of the pathology of ovarian tumours, I shall next call your attention to the consideration of what is of even greater importance to the practical physician, namely, their diagnosis, a matter often of the greatest difficulty, and an error in which may entail the most serious consequences, jeopardising and even sacrificing life itself. The general symptoms which usher in ovarian disease are very vague and uncertain. The patient may and indeed probably does complain of a considerable amount of discomfort in the ovarian region before being conscious of any actual ailment, but as a rule the first thing which attracts her attention is the discovery of a tumour or at least a fulness in one side of the abdomen which gradually increases in size. But often even when it has reached this size the patient does not pay any attention to her state or seek medical aid. The patient at present in hospital under Dr. Walsh's care, as well as that recently operated on by Dr. Barton, are examples of ovarian tumours following this course—the former, a married woman, aged thirty-five, tells you that about two years ago, while in the enjoyment of perfect health she perceived a tumour about the size of an orange to exist in the left side of the abdomen, that it was painless, only causing a kind of uncomfortable feel, and was so moveable that she could push it quite from one side to the other of the abdomen without difficulty. This tumour slowly increased in size, and after the lapse of four or five months began to cause her a good deal of distress. She also suffered constantly from a dull aching pain in the side, which occasionally became so severe that she had to apply poultices and mustard blisters

with the view of obtaining relief. Till about six months ago she was able to move the tumour, but since that date it has become quite fixed. Menstruation has always been regular, both as to the time of its appearance and the quantity of the discharge; latterly the appearance of the flow has brought her a certain amount of relief. The history of Dr. Barton's case was in many respects similar. She was of nearly the same age as the other patient, being thirty-six; was married and had given birth to two children, the youngest being eight years old. About two years ago she also noticed a small globular tumour in the left side, which has ever since steadily enlarged. These two examples of ovarian disease which are strikingly alike in their general outline are typical of a large class of cases. But sometimes the tumour escapes observation till the size which the abdomen has attained attracts the patient's attention; this is specially likely if the disease occur simultaneously with pregnancy. Mr. Spencer Wells records several examples of this.

In addition to the symptoms enumerated there are often various others present referable to pressure on the neighbouring viscera, such as irritation of the bladder, or interference with defecation; but these are always vague, and for the purpose of diagnosis valueless. More definite and more important are the paroxysmal attacks of pain from which the patient not infrequently suffers. These may be due to the tension of some of the folds of the peritoneum, but they are far more frequently caused by transitory attacks of local peritonitis, and as a result we often find intimate adhesions formed with the surrounding structures, especially with the omentum, and these adhesions add greatly to the difficulty, as well as to the risk, of operations undertaken for the extirpation of these tumours. In the vast majority of cases however the disease has advanced to a stage in which either a well-defined tumour or distinct fluctuation, or both, exists in the abdomen before we are called on to give a diagnosis as to the nature of the disease from which the patient suffers. This was so with both the cases recently in this Hospital—in both large tumours and evident fluctuation existed for a long time prior to their seeking medical aid.

When this stage has been reached the general health nearly invariably suffers to a greater or less degree. In the patient at present in hospital, and on whose case I am specially commenting, it was merely to the extent of loss of flesh, while in the other there was great emaciation, accompanied by dyspnoea, the result of the size of the tumour also loss of appetite and a long train of secondary symptoms. Menstruation may continue to be normally performed, this was so in the patient whose case we are considering, but in many it becomes irregular as the disease progresses, or is altogether suppressed. When this occurs the patient, if she be married, naturally attributes the increased size of the abdomen to pregnancy, and even in unmarried women, as occurred in the well-known case of a lady of rank, the unjust suspicion of pregnancy and its attendant disgrace has been attached to the sufferer, an injustice which the exercise of but a moderate amount of skill should have prevented.

The leading features of a case of ovarian cystic disease then are these: we have a tumour of variable size, the gradual growth of which has generally been traced by the patient. The surface in the case of the unilocular tumour is smooth and even, while in the multilocular the separate cysts impart a lobulated irregular feel to the hand passed over the abdomen. Fluctuation is generally distinct in the former and can be felt everywhere over the surface. In the latter this is only the case here and there, or it may be detected in but one situation, while in them we can also nearly invariably make out at some point a firm hard mass, indicative of the existence of solid matter. The whole of the anterior surface of the abdomen is, in the case of either form of ovarian disease, dull on percussion, the intestines being forced back behind the tumour. A vaginal examination which should in all cases be made, will prove the uterus to be of its natural size and shape, but in many cases that organ

is displaced, being drawn upwards and anteflected, but this is far from being invariably so. The conditions or affections with which cystic disease may be confounded are numerous. Extra-uterine foetation, ascites especially if complicated with the existence of an enlarged spleen, tumours of the omentum and cancerous tumours in various situations are liable to be mistaken for ovarian disease, but this has specially been the case with regard to fibro-cystic disease of the uterus. Of twenty-three cases recorded by Mr. Clay, in which ovariectomy had been attempted but in which the operation was abandoned in consequence of the disease proving not to be ovarian, twelve were uterine in two no trace of a tumour whatever could be found, while the enlargement of the abdomen from the presence of an ovarian tumour, when menstruation is absent may easily give rise to the idea of pregnancy. It seems hardly possible that an impregnated uterus could be mistaken for an ovarian tumour, yet this mistake has been made, and in order to guard against the recurrence of a similar error you should invariably seek for the usual symptoms and signs of pregnancy, some or all of which will be sure to be present in a more or less marked form. A careful vaginal examination will prove the uterus itself and not the ovary to be the seat of the enlargement. This is one of those cases in which the practice of ballotment may possibly be useful; you must however always bear in mind that pregnancy is not incompatible with the existence of disease of at least one ovary. The diagnosis between ascites and ovarian dropsy is not in general different. It is with the simple unilocular form that the question is most likely to arise. The history of the case often aids us materially in forming our opinion, for the patient is frequently able to tell you that the swelling commenced at one side by the gradual enlargement of a small tumour, which continued to increase till it extended across the abdomen, a history which would be incompatible with the idea of ascites, in ovarian dropsy also there is almost invariably dulness on percussion over the whole front of the abdomen.

The very reverse of this occurs in ascites, for in that disease the intestines are almost invariably in contact with the anterior abdominal wall, and consequently percussion there yields a resonant sound, fluctuation too is most clearly felt laterally in the lumbar regions in ascites, that being the point at which it is likely to be wanting in the case of "Ovarian Dropsy."

I cannot however go further into these details, much less would it be possible, even if it were desirable for me to enter on the consideration of the differential diagnosis between ovarian cystic disease, and that of all the other affections with which it may possibly be confounded, and I must content myself with having laid before you the distinctive features of the former. Your other clinical teachers will explain to you those of the others, and you must for yourself weigh the relative value to be assigned to each symptom when called upon to decide as to the nature of the affection from which the patient suffers. But it is essential before passing from the subject of diagnosis that I should point out to you the principle distinctive feature which exists between ovarian disease and fibro-cystic degeneration of the uterus; first, because both diseases are strictly within the limits assigned to the obstetric surgeon; and secondly, because the latter is that which is specially liable to be mistaken for the former, and indeed so closely simulates it, as to mislead the most careful observer.

I have in a previous lecture given you an outline of the leading features of fibro-cystic disease of the uterus, and I think I shall best aid you now by throwing these into contrast with those of ovarian disease, so as to present them to you in a kind of tabular view, premising however that there is not one of the symptoms enumerated which is not liable to great variation, and that therefore the most extreme caution must be exercised in forming an opinion based on them. I should also add that I am now speaking only with reference to tumours

of considerable size, and which extend entirely or very nearly across the whole abdomen.

*Ovarian Cystic Disease*      *Uterine Fibroid and Cystic degeneration.*

May occur at any age, but probably more frequent before the age of thirty-six than after it. Of 231 cases recorded by Mr. Clay, and of which the ages were known, 168 were under thirty-six, sixty-eight of these were aged between seventeen and twenty-five years.

Previous history often throws light on the diagnosis, a tumour being frequently felt at one side, and which has gradually extended across the abdomen.

Growth of tumour comparatively rapid.

Menstruation sometimes normal, but frequently irregular, and as the disease progresses is liable to be suppressed profuse menstruation of rare occurrence.

Uterus of its normal size frequently drawn upwards, so as to be difficult to reach and anteflected and moveable unless bound down by adhesions.

Tumour becomes softer as it increases in size.

Urine voided without difficulty.

Generally health always suffers more or less sometimes to a great degree.

If care be taken to weigh each of the distinctive features here enumerated, the risk of making a serious error in diagnosis will be greatly lessened, above all let me impress on you the necessity of your using the uterine sound.

It affords us the most important aid in forming our diagnosis. In the great majority of cases of large fibrous growths from the uterus, whether solid or fibro-cystic, the uterus is either embedded in or so firmly attached to the tumour that it cannot be moved independent of it, a point which can easily be ascertained by inserting the finger into the rectum and keeping it there, while the sound previously passed into the uterus is rotated gently, and again the sound should be held steadily, while an assistant endeavours with both hands to rotate the tumour itself, a manipulation which often enables us to decide whether the uterus be attached to the tumour or not.

Still even here error is possible, for if a fibrous tumour spring from the uterus by a moderately long pedicle, or even by one as short as that shown in Plate VI., we may

Rarely met with in early life, of twenty-three cases recorded by Mr. Clay in which the operation was abandoned in consequence of the disease being extra ovarian, thirty-four was the age of the youngest patient.

Such a history unlikely to occur, growth usually more central.

Growth comparatively slow.

Menstruation normal, if tumour be sub-peritoneal likely to be profuse, if in substance or interior of uterus.

Uterus elongated, if tumour be in substance or interior. Sound often passing for a considerable distance into its cavity, when tumour is detected, sound moves with it.

Time not likely to alter consistence of tumour.

Difficulty in passing water occasionally experienced from pressure on bladder and urethra.

General health does not suffer unless menorrhagia be present.

be able to move the uterus to such an extent as to the conclusion that it was free, and on the other hand it is possible that in a case of ovarian disease the uterus might be so bound down by adhesions as to be immovable.

An abdominal tumour had been discovered five years ago, which during the last six months had increased rapidly. On admission into hospital a large tumour was felt which evidently contained no cyst large enough to warrant tapping, but which did not feel so hard as a fibroid tumour of the uterus, no vascular murmur was audible, and it appeared to move quite independently of a uterus of normal size. When the tumour was exposed it proved not to be ovarian, it sprang from upper part of the posterior surface of the fundus uteri short pedicle. The tumour was removed and was found to weigh thirty-four ounces, and was seven-and-a-half inches in diameter, the fact of the tumour growing from almost the very fundus of the uterus doubtless permitted that organ to have a greater amount of mobility than is usually met with in such cases, and when I add that the operator was Mr. Spencer Wells, you will agree with me that no means were omitted by that distinguished surgeon for arriving at a correct opinion as to the nature of the tumour.

### CATECHU AND OPIUM AS AN ASTRINGENT IN GLEET.

By R. LOCKE JOHNSON,

Visiting Physician to the Infirmary for Consumption and Diseases of the Chest, Margaret street, Cavendish square.

In March last a City gentleman, whose daily avocations are of so arduous a nature as to require his personal attention for more hours than are generally considered advisable for such persons as desire to keep a healthy mind in a healthy body, consulted me for a pulmonary affection, by which he had been seized for the first time. The affection yielded to ordinary treatment, and, at my earnest solicitation and persuasion—for patients, when they assume even a moiety of former vigour, as a rule do not feel disposed to adopt, *per saltum*, medical advice—arranged his affairs in such a manner as to enable him to take in the country a month's holiday—a luxury to which he was quite unaccustomed. My patient has had no reason to regret his month of idleness, in so far as relates to the complaint, for which relaxation from business was advised; but, during his sojourn in a fashionable watering-place, he contracted—by "inadvertence," he states—a gonorrhoea of no mean character. He tells me that this gonorrhoea was extremely difficult to be got under, and since its decline, nearly three months past, he had been afflicted with a troublesome gleet, on which neither injections nor medicines administered by the mouth exercised any influence.

Examination of the urethra revealed to me the usual semi-viscid discharge, which I was informed exercise, excitement, or stimulants of any kind influenced very much. There was no trace of inflammation at the orifice or along the line of the urethral passage; but, my patient said, he felt occasionally, about a thumb's breadth from the orifice, a small elevation which he considered influenced the discharge and subsided with it. There was neither pain nor heat experienced during or after micturition, and he suffered merely from the inconvenience experienced in ordinary cases of gleet.

I prescribed for him an astringent injection, composed of tinct. opii, ℥j, tinct. catechu, ℥jss., and misturæ acaciæ ℥ij, to be used twice daily.

The discharge ceased after the second application of the foregoing, and has not re-appeared, and I note the case as one of a series of simple but persistent gleet similarly treated by me.

## Hospital Reports.

### Case of Fracture of the Base of the Skull; Paralysis of Abducens; Recovery.

(Under the care of HENRY HADLOW, Royal Naval Hospital, Yokohama.)

[This case has been communicated by the Director-General of the Medical Department of the Royal Navy to a Contemporary.]

J. C—, able seaman, of H.M.S. *Rinaldo*, on October 26th, 1870, fell from the fore-topmast cross-trees into the fore-top, cannoning against a man in his descent, falling obliquely on the right side of his head. He was picked up unconscious, with blood flowing profusely from the ears, and was at once brought to the Naval Hospital. When received the coma was found not complete; he could be aroused if loudly spoken to; the pupils were dilated, sluggish, but not insensitive to light, and blood was flowing freely from the ears. This flow of blood, and afterwards of blood mixed with yellowish fluid, continued for three days, and ceased on October 29th. On November 2nd he was found to present slight but sufficiently marked internal squint of the left eye. No other cerebral symptom. The squint increased daily. On the 21st of November, the report is, "Looking at an indefinite far point directly before him, there is inversion to the extent of an English line. He cannot evert the eye beyond the centre point or 0 of the strabismometer; there is lateral diplopia except when looking to the extreme right, and asthenopia.

After this date he began to improve. On December the 14th the inversion had diminished to half a line. He had acquired the power of abduction to the extent of nearly two lines. The sight of the eye was good. He could read No. 20 Jaeger at twenty-two feet, and accommodation was unimpaired,  $\frac{1}{3}$ ; diplopia continued, except when looking considerably to the right of the middle line. He improved slowly but steadily. A month after the last date, images of objects immediately in front of him were coincident, and he had power of eversion to the extent of more than two lines.

On the 18th of February, abduction could be effected completely, and the only want of parallelism between the optic axes was about twenty degrees to the left of the direct centre. "On the 8th of March he was quite well, the optic axes coincident at all angles, and with perfect binocular vision when tested with the stereoscope.

In Holmes's "System of Surgery," two cases of paralysis of the sixth nerve alone, following fracture of the skull, are given. One terminated fatally, and the other was operated on for the resulting squint without any good result. A case of complete recovery following this accident appears worthy of being placed on record.

## BRITISH ASSOCIATION

FOR THE  
ADVANCEMENT OF SCIENCE.

FORTY-FIRST MEETING, HELD AT EDINBURGH.

### ILLEGITIMACY.

MR. SETON read three papers on the following subjects:— "On certain cases of Questioned Legitimacy under the operation of the Scottish Registration Act;" "The Illegitimacy of Banffshire;" and "The Expediency of recording Still Births." The first paper referred to the subject of adulterine bastardy. It touched upon the conflict between the legal presumption in favour of a child born in wedlock being the lawful issue of the spouses and the mother's conviction of its illegitimacy. The course to be followed in the registration of such cases

was pointed out. The second paper gave elaborate details regarding the illegitimacy of Banffshire during the four years ending 1861, and embraced a supplementary appendix relative to the four years ending 1869. Amongst other things, it was mentioned that, with a few rare exceptions, the county of Banff has always exhibited the largest percentage of illegitimacy—viz., about 16 per cent., the ratio for Scotland generally being between 9 and 10 per cent.; that very considerable differences exist in the different parishes, the maximum rate being upwards of 25 per cent., and the minimum as low as 6 or 7 per cent.; that as a rule the seaboard parishes have a lower percentage of illegitimacy than the inland ones; that neither the excess of females over males, nor the comparative number of houses and windowed rooms (as ascertained at the Census) afford very satisfactory solution of these differences; and that with regard to the county generally the comparative paucity of marriages may perhaps have something to do with the larger amount of illegitimacy. The paper also contained particulars relative to the occupation of the mothers of illegitimate children, the number of cases in which the paternity was acknowledged at registration or found by decree of court, and the number of children legitimated by the subsequent marriage of their parents. The third paper mentioned that, while still-births are recorded in France and some other Continental countries, they are not registered either in England or Scotland. It was stated that the still-births in Glasgow during the three years subsequent to 1849 were estimated by the late Dr. Strang to have amounted to one in twelve, or upwards of 8 per cent. In France the percentage amounts to between 4 and 4½ per cent., and in Paris to about 7½ per cent. The ordinary proportion among legitimate children is from 1 in 18 to 1 in 20 of all births, and among illegitimate children three times greater. More males are still-born than females—viz., 140 to 100. Reference was made to the difficulty of defining the terms "still birth" and "viability," to the supposed prejudices against the registration of still births; and the desirableness of their being recorded on the ground of public policy and in the interests of medical science was adverted to. The paper concluded with a recommendation that the experiment of such a registration should be tried in Scotland, and some practical suggestions were given as to the mode in which it ought to be carried out.

SIR JOHN BOWRING took occasion to refer to foundling hospitals as preventives of infanticides. He said he had lived in a country where little respect was paid for human life—in which children were bought and sold like cattle in the market place, mothers selling their children for a few pence. It was difficult to dispose of females on account of there being such a large number; and he knew of an eminent man in China who had written a book in which he maintained that it was the duty of mothers to destroy their infant daughters rather than allow them to grow up to a life of profligacy and misery. He had seen ponds filled with children; and in some of the cities he saw pillars with holes in them, and the inscription—"The receptacle for toothless children." Now, notwithstanding these things, there were large hospitals for foundling children. As far as his observations went, the destruction of life was much greater where these hospitals existed. The sacred feeling by which the mother was bound to take care of her child was destroyed by legislative provisions and public opinion. They had one of those institutions in London, and the inhabitants were very proud of it; but he believed that to a very great extent that foundling hospital was filled by the unhappy consequences of vice and profligacy. He hoped Mr. Seton would consider that branch of the question, and bring the subject before the Medical Association. (Hear, hear.)

MR. A. E. MACKNIGHT said the system of giving relief to women with illegitimate children had exercised a demoralising effect on the country, and he hoped the plan which formerly obtained in Scotland would again be adopted—namely, to cause the mother or her friends to support the child when the father could not be found.

MR. VALENTINE was of opinion that illegitimacy in Scotland was on the decrease, and not on the increase. It was the greater prominence which the modern system of statistics gave to the evil which made people think it was on the increase. If they read the old records of kirk-sessions, they would find that this evil was diminishing in the country.

MR. J. JACK said he came from Aberdeenshire, and it was his opinion that illegitimacy had greatly increased within the past fifty years. He feared that the unenviable prominence of Banffshire in this respect was the result of the neglect of the moral training of the young. In the schools carried on

under the "Dick Bequest" in that quarter of the country, the scholars received a strictly literary education, without any religious teaching, and he believed this operated prejudicially on the morals of the pupils.

#### CHILDREN HOSPITALS.

DR. WILLIAM STEPHENSON read a paper "On the Scientific Aspect of Children Hospitals." He said that the Edinburgh Sick Children's Hospital was established eleven years ago to provide for the reception and medical treatment of the children of the poor during sickness, and to promote the advancement of medical science, with reference to the diseases of childhood, and to provide for the more efficient instruction of students in this essential department of medical knowledge. At present it contained 74 beds—32 for ordinary patients and 42 for fever cases. Children hospitals, he said, were needed for scientific requirements, and to arrive at any important clinical results they had to group together large numbers of cases, such as could only be done in hospitals of considerable size. It was recommended that students should be made to study the diseases of children before receiving their diplomas, and reference was made to the advantages of such an institution for training nurses.

LORD NEAVES said there could be no doubt of the importance of the Children's hospital to the medical school; but he said that such an institution would have a prejudicial effect on society if parents were to be allowed to take their children there whenever they were ill with measles or whooping cough. In the administration of these hospitals, they must take care that in relieving special cases they did not give encouragement to improvidence.

DR. DAVID MURRAY said he believed that the outdoor department of the Edinburgh Hospital for Sick Children did a great deal of mischief. Parents brought their children labouring under dangerous diseases to the hospital, where they were collected in groups, and the effect was to spread the diseases.

#### THE WELLINGTON REFORMATORY.

SHERIFF CLEGHORN read a paper "On the Wellington Reformatory," in which, among other things, particulars were given regarding the industrial training the boys received.

In the discussion which followed, several gentlemen spoke of the advantages of industrial training.

The section adjourned at three o'clock.

#### MUSCULAR ANOMALIES ON THE DARWINIAN THEORY OF THE ORIGIN OF SPECIES.

PROFESSOR MACALISTER read a communication on "The Bearing of Muscular Anomalies on the Darwinian Theory of the Origin of Species." He said that three arguments from anatomy are usually brought forward in support of the evolution theory of the origin of man. The first of these is derived from embryology, the second from rudimentary structures, and the third from anomalies. The object of this paper is to endeavour to determine the precise value of the last of these arguments. This may be stated thus—It is the experience of anatomists that structures are variable; that in scarcely two subjects are parts similar to each other, and often very great varieties are noticed. As these varieties simulate the normal arrangements in lower animals, it is inferred by some that they are evidences of a genetic affinity. The first point to determine is—Do the anomalies of parts in man resemble the normal structure of lower animals? The evidences in determination of this point were drawn by the author from the muscular system, and he classified muscular anomalies according to the relation to lower animals. The first class consists of these separate muscles which are normal in lower animals, and only merely present in man; such are the muscles known as occiput, scapular, peroneous, quints, levator clavicule, &c. The second class consists of those separate muscles which exist as anomalies in man, but do not exist as normal in lower animals, such as the sixteen abnormal laryngeal muscles described by different authors. The third class consists of such muscles as are distinctive of man, and which are sometimes anomalously absent in him, and still more rarely some of the peculiarly human muscles are present as anomalies in lower families. The fourth class consists of muscles common to man and other animals, but which normally are differently arranged in both. In man such muscles are often found arranged according to lower animal types, and this class contains by far the largest number of anomalies. How to account for these anomalies has long been a subject of dispute. There are two hypotheses which seem competent to account for them. One large series, like the second class,

is accounted for on functional grounds, but this hypothesis is incompetent to explain the occurrence of all, as some anomalies are sources of weakness, and absolutely destroy function. That function is a factor, however, seems plain, from three considerations—(1), The muscles which have a great variety of function have a wide range of variation; (2), muscles which have no function, like those of the whale's paddle, are very valuable; (3), those muscles which have single definite functions vary very little. The second hypothesis is that of reversion—that such anomalies are produced by the tendency to revert to some earlier structural condition of some further stage of parental condition.

Mr. BOGE said the question was—What was the intention or aim of these anomalies? The answer of Professor Macalister is, that they are either most complex or of primary forms. He thought there was another answer, and though it might seem extraordinary, he hoped they would allow him to regard man as a microcosm—as a little universe, having in his mind as well as his body the characteristics of the law of creation, and having these anomalies retained in his structure to indicate that he is evolved not from the lower animals, but that the Creator evolved the lower animals from Himself, and that as he could not create any animal which had no connection with the Person who produced it, they could not exist without having their own structure in the present state as types of those which exist in God, and consequently of man, who is the image of God. (Applause.)

PROFESSOR MACALISTER said he preferred to adhere to a negative rather than the positive side of the argument—that is, he tried to reduce the evidence as much as possible, that without a hypothesis of evolution they could not explain these anomalies. He therefore thought they were shut up at present to the evolution hypothesis; and the proper way to pursue this investigation further would be to tabulate all the muscular anomalies in man, and do the same in regard to the lower animals, and compare the two so as to consider whether the grouping of anomalies in man was the same as in the lower animals. He had drawn out such a table regarding man, and would leave it to some one better qualified than he was to make out a similar table regarding the lower animals.

The PRESIDENT said the section was not only very grateful for his interesting paper, but for presenting them with an example of how such a subject ought to be treated, and how the collection of anatomic facts was to be brought to bear on the hypotheses on this subject.

#### VENTILATION AND VITALITY.

Mr. J. D. MORRISON submitted the following paper "On a New System of Warming and Ventilation":—At the meeting of the British Association at Exeter, Professor Archer very kindly read for me a paper descriptive of my system of ventilation applied to dwelling-houses. To-day I intend to call your attention to other applications most intimately connected with sanitary science. In carrying out my system, I have had forced on my conviction the very close relationship between ventilation and vitality, which form the subject of this paper. That the relation may more clearly appear, I shall, with your kind permission, read to you, from page 219 of the Association's Transactions of 1869, the short outline of my system by the editor:—"The main features of this novel system of warming and ventilating consist in so circulating pure fresh air (through a warming chamber) into the room, and of foul air (through the fire) into the chimney, that all local currents are resolved into one, which, describing an unbroken circuit, forms an upper warmer current from the fire to the opposite wall, and an under colder current (under the floor) from the wall back again to the fire, when, after supporting combustion, the products escape up the chimney. The vacuum thus produced by the warmer current through the chimney, creates the now colder current from the atmosphere, which, passing through the heating-chamber, supports the respiration of any number of individuals." From this extract you will readily perceive that, imitative of nature, I produce, by mechanical means, an artificial trade-wind. Commingled with this air in motion, I propose to carry, in a circuit and by a current, the conditions of life to plants and animals—firstly, by an outward current from any centre to any circumference, to carry the conditions of life to them; and, secondly, by the veins of the returning current of the circuit, to remove from them their exhalations. For several years I have had in contemplation the carrying out of such a system, in exact imitation of the currents of the atmosphere

and the circulation of the blood; and reflecting over the fact that one grain of musk has been known to perfume a room for thirty-six years without sensibly losing weight, it occurred to me to take advantage of this extreme divisibility of matter in nature, and, by copying her in other respects, to carry by artificial appliances all such substances as by solution in spirit, water, or other simple mediums can be so divided, and consequently evaporable into any current of air passing over them. Acting on this thought, to carry by a current of purified air any amount of required heat, moisture, or medicine to the lower animals, and from them their exhalations, I submitted at the last meeting of the Highland and Agricultural Society of Scotland my proposal to the test of the judges, and had the satisfaction of being by them awarded the society's medal. Encouraged by this mark of approval of my efforts, I have built an addition to my house, so that one room, in particular, may be placed at the service of the medical profession to test, by actual experiments on climate, the power of pure, fresh air, chemically-pure water, heat, light and exercise on the human system. Through this room a general current of air passes and commingles, consisting of a purified and warmed current across the entire floor, rising to meet a descending cooler and purified current from the entire ceiling; these, having intermingled, support respiration, and then pass, by a ventilating shaft, to be burned in the fire. After thus supporting combustion the products pass into the chimney. Into this general current I can at will diffuse, by a branch circulation, a second current, which, having passed through a solution of any medicine, joins the main current, and is now inhaled as perfumes are from flowers.

### THE THIRTY-NINTH ANNUAL MEETING

OF THE

### BRITISH MEDICAL ASSOCIATION,

Held at Plymouth, August 8th, 9th, 10th, and 11th, 1871.

President: JOHN WHIPPLE, Esq., F.R.C.S.

#### ABSTRACTS OF PAPERS READ IN THE SEVERAL SECTIONS.

DR. JOHN MURRAY read a paper on

#### CHOLERA: ITS DIFFUSION, PROPHYLAXIS, SYMPTOMS, AND TREATMENT,

in which he said his opinions are supported by a very great majority of the medical officers now in India, as shown in a recent report submitted by him to the Indian Government, in which the opinions of 505 medical officers are carefully tabulated.

In no malady, he said, are there more marked and characteristic symptoms than in cholera; but the symptoms, which are only found in one stage, are so dissimilar to those induced by the poison in an earlier stage or mild attack, that the connection has by many been overlooked.

The earliest symptoms that can be recognised are those of *malaise*, viz., depression of spirits, want of appetite, torpidity of the bowels, and desire for stimulants. That this *malaise* is caused by the presence of the poison of cholera is an opinion strengthened by the fact that, during an epidemic attack, when this feeling exists, the action of a purgative—especially salts—will almost always be followed by the other symptoms of cholera, and the circumstance of the frequent occurrence in men who have left the infected locality in apparent health and have been attacked within one or two days.

To the symptoms of *malaise* succeed *diarrhoea*, nausea, and vomiting; the urine is scanty; the stools light-coloured, then colourless, like rice-water, with occasional cramps, heart-burn, and slight headache. The countenance is dark and the eyeballs congested. This is followed by *collapse*, great prostration of strength, burning in the epigastrium, congee or rice-water vomiting and purging, with cramps and suppression of urine; cold clammy perspiration, feeble pulse and cold breath, broken voice and shrunk and livid face. When reaction takes place, the burning pain in the epigastrium disappears, the restlessness subsides, the stools become coloured, urine is

ecreted, warmth returns to the palms of the hands, the colour improves, the pulse becomes stronger, and sleep ensues.

In many instances the disease does not progress beyond the stage of *malaise* or *diarrhoea*. The poison appears to be digested or eliminated by the *vis medicatrix naturee* through the natural functions of the system—hence the great importance of supporting these, and avoiding their being overtaxed, exhausted, or depressed.

Cholera is a specific disease, caused by the presence of a specific poison in the system; it multiplies or is reproduced; it must be vital and amenable to the ordinary laws which regulate other specific poisons, modified by the peculiar structures of the body which are chiefly affected. It must enter the body through some of the ordinary channels. Before health can be restored, it must be eliminated either in a vital state or after being decomposed or digested.

The poison leaves the body through the same channels by which it enters; viz., the bowels, the lungs, and the skin. Its presence in the discharges from these organs is recognisable in most instances by the smell—a mawkish, sickening odour, well known to those who have seen much of the disease. In the earlier stages the poison appears to be destroyed, or digested, without exciting any active symptoms, and this is the safest way of nature getting rid of it. The first active symptom is diarrhoea; and here we can be useful, as the system during this stage is amenable to remedies.

All experience of the course of the disease teaches us that it rages with the greatest intensity, and proves most fatal where people are collected in great numbers—where there is crowding and filth, defective ventilation and impure water; and that it is aggravated by want and bad food.

Sanitation is of the greatest importance in the precautionary treatment of this epidemic, in ameliorating the virulence of the attack, restraining its dissemination, or warding it off entirely.

There is another point of no less importance in the precautionary treatment, on which the profession was not in former years so unanimous: the contagious nature of the disease, meaning thereby the transmissibility, directly or indirectly, of the specific poison from a sick to a healthy person. In India there were only five hundred and five medical officers who stated that it is not communicable. There is a slight divergence of opinion regarding the channel through which the communication takes place, and the changes undergone by the poison after leaving the diseased person, but none as to a diseased person being a source of danger if admitted into a healthy locality.

There has been a great diminution of mortality from epidemic cholera in India, particularly amongst the European troops, and in the gaols, since precautionary measures founded on these indications have been carried out. In many cases, cantonments and prisons have remained free from attack whilst the disease has raged amongst the population of the surrounding districts, and the mortality has been materially diminished in most of the stations where it did break out; still, in several stations and gaols where the sanitary arrangements have been carried out by most efficient officers, there have been very severe and fatal outbreaks of the disease, particularly in the cantonments of Peshawur, Kohat, Allahabad, and Gwalior, and in the Central Prison at Agra, which has long been celebrated for the completeness of its sanitary arrangements.

The removal of troops or prisoners is a simple process in India. The supply of tents and means of carriage is ample, and the surrounding country open. In small villages the inhabitants desert their homes and live in the open air; and many who have the means leave the large towns. The precautionary arrangements in towns have been limited to the construction of special cholera hospitals and the general distribution of medicines. People have generally a great aversion to leaving their homes and entering a cholera hospital; but these hospitals were generally filled with travellers and poor people. The free use of disinfectants applied to the evacuations has been employed with marked advantage.

I do not wish it to be inferred that I think it as communicable as many other diseases, or that there is *very* great danger in attending on the sick, especially in Great Britain, where decomposition is comparatively less rapid than in India. I have attended thousands of cases, and only contracted the disease three times, which yielded readily to early treatment. The exemption of hospital attendants, where prompt treatment is available, is remarkable; and the number of relatives and friends who attend in private houses and

escape, or only have very slight indisposition, is generally observed.

In the stage of *malaise* the poison is thrown off without any violent or very prominent symptoms by the natural functions of the system. Our task here is to support the strength, avoid indigestible food and depressing causes. The only medicine that I have found useful in this stage is a little quinine every day. The subsequent indications of the treatment are to remove the abnormal symptoms as they appear, of which the most early is *diarrhoea*. The first indication is to check this and restore the case to the stage of *malaise*, then remove the cause and restore the natural secretions. Irritating or indigestible food in the bowels is the most frequent cause of diarrhoea; and should this not previously have been discharged in the evacuations it should be removed and a recurrence of the looseness guarded against, as I have always found it the most powerful exciting cause of collapse. I have found this best carried out by a combination of opium with carminatives in the form of a cholera pill, composed of one grain of opium, two of black pepper, and three of assafœtida. It appears to check the looseness and stimulate the secretions. This pill does no harm if needlessly administered. It should be repeated should the looseness continue. It will cure most cases, and in all restrain the symptoms until regular medical advice can be procured. This is a most important point in the use of this simple remedy. It may be distributed to every house and be available in a few minutes, whereas the delay of a few hours may allow the disease to advance beyond control. I know no better remedy for this stage. These pills have been distributed in tens of thousands in the towns and villages of India with most satisfactory results. Some surgeons prefer red to black pepper, and others add camphor to the opium and assafœtida.

In collapse, our power is limited by the circumstance that the vital organs are insensible to the ordinary action of medicines. Experience shows that opium, astringents, and alcohol, lie inert in the collapsed stomach, though these are the ordinary remedies for pain, looseness, and debility. It is also my experience that the free use of these remedies at this stage causes death, either by preventing reaction, or by causing local complications should reaction appear.

There is another cause of death which is not generally understood, but which it is in the power of all sufferers or attendants on the sick to check or to prevent. I allude to the extreme danger of assuming the erect posture, or even of sitting up in bed, during collapse, or the earlier stage of reaction. I have seen myself, and I have heard of many cases, where fatal syncope instantly followed sitting up in bed or rising to go to stool.

The first sign of reaction is coincident with the appearance of bile in the evacuations. The dilution of the irritating contents of the bowels and the restoration of the watery particles of the blood are indicated and best fulfilled by frequent small quantities of cold water, to which a little soda or carbonate of ammonia may be added with advantage. In protracted cases I have seen decided benefit from the use of Liebig's extract of meat, made fresh and given frequently. I have also seen most marked benefit from the exhibition of hot saline enemata given after each motion. In some instances it has acted like magic, the symptoms subsiding after one injection, but in many others they have been powerless. I have thought that the artificial supply of Nature's own remedies in the stage of *malaise*, the secretion of which is suspended by the action of the poison as the disease advances to collapse, might be useful, and the results in a few cases in which they were used previous to my departure for India were highly satisfactory; seven out of nine having recovered, and the two fatal cases having been pulseless and dying before the remedies were used: these remedies were gastric juice and bile, in the form of acidulated pepsine, fifteen grains, and inspissated bile fifteen grains, given alternately every hour. The dose of bile was followed by vomiting; but bile soon appeared in the evacuations, and mild reaction set in gradually. Shampooing with warm turpentine liniments gives relief to the cramps, and mustard poultices on the epigastrium restrain the vomiting. I think I have used a little quinine with advantage when Nature made an effort at reaction.

The practice is generally condemned in India. Calomel I have found inert in collapse, both in large and small doses, and consider that the benefit attributed by many to its use arises from its being employed instead of spirits or strong remedies. There is danger of its being accumulated in large

quantities when reaction takes place. Sulphuric acid and acetic acid are less dangerous; but I have not seen decided benefit from their use. I have not found advantage from ammonia, except when added in small quantities to the cold water. I found, in 1833, the transfusion of saline fluids into the veins caused most hopeful reaction; but it was only temporary, and this is the general result of numerous trials made by other medical officers in India. Brandy I consider dangerous in proportion to the quantity given in the stage of collapse, and opium as decidedly poisonous in this stage. Chloroform, though it may give temporary relief, tends to induce dangerous head symptoms on reaction. Astringents are not beneficial. Purgatives are dangerous in the earlier stages, and not useful in collapse; they are generally condemned in India. Heat has been extensively tried by warm baths, but the fatigue entailed is dangerous. It has been tried in the form of hot-air baths, but the result has not been encouraging.

When reaction takes place, rest and careful nursing will complete the cure where collapse has not lasted long; but in protracted cases, in addition to these remedies, medical treatment may be required for low fever, remedia, or local complications, regulated by the ordinary rules.

DR. WILSON FOX read a paper on

TREATMENT OF HYPERTYREXIA, AS ILLUSTRATED IN ACUTE RHEUMATISM, BY THE EXTERNAL APPLICATION OF COLD.

He said cases of acute rheumatism in which, after a course of variable severity, the temperature suddenly rises from  $103^{\circ}$  or  $104^{\circ}$  to  $107^{\circ}$ ,  $108^{\circ}$ , or  $109^{\circ}$ , have usually proved fatal within a very short time after the latter temperature ( $109^{\circ}$ ) has been attained. In the majority, indeed, of published instances this has been the case within one or two hours; and Wunderlich regards this terminal rise as "progonic," or as one of the phenomena of death—a view still further borne out by the fact that a further elevation is often continued for one or two hours after life has apparently ceased.

He published last year a case in which, by means of repeated immersions in the cold bath, life was protracted for nearly thirty-six hours after the patient's temperature, while suffering from acute rheumatism, had reached  $109^{\circ}$ , death finally taking place by exhaustion at a temperature of  $104.4^{\circ}$ . This case had been complicated by a large bleeding, practised before the bath was employed, in the hope of thereby producing a reduction of temperature, when this had reached  $109^{\circ}$ , and when the patient was violently delirious. Venesection to more than twenty ounces had no effect whatever in checking this rise; and the hope was expressed that cases of this nature, treated by the cold bath and without venesection, might yet show a favourable termination, and this hope, has been realised in two cases. The patients, a man and a woman, have completely recovered under this treatment, after rapidly attaining a temperature, in one case, of  $110^{\circ}$ , and, in the other, of  $107.3^{\circ}$ . Both were first attacks of the disease; and, indeed, this ordinarily fatal mode of termination appears to be more common under these circumstances. The cases were detailed.

DR. WM. ROBERTS (of Manchester) read a paper "On Intemperance as a cause of Chronic Bright's Disease." The author said that the generally received opinion that the abuse of alcoholic liquors is a frequent cause of Bright's disease has been called in question by Dr. Dickinson, in an elaborate argument in his recent work on "Albuminuria;" and the scope of the paper was to examine the evidence on which Dr. Dickinson had relied in coming to an opposite conclusion. Dr. Roberts endeavoured to show that the pathological facts adduced by Dr. Dickinson were either untrustworthy or that they had been incorrectly interpreted. As to the argument drawn from the reports of the Registrar-General, Dr. Roberts admitted as Dr. Dickinson had stated, that the districts which yielded the largest returns of deaths from intemperance did not return an excessive proportion of deaths from Bright's disease; but exactly the same result was obtained when the same statistics were applied to the mortality from cirrhosis of the liver—a disease which is notoriously and chiefly the product of intemperance.

DR. E. J. TILT read a paper "On Hysteria and its Various Interpretations," in which he spoke of hysteria as the product of an indispensable predisposition to emotion on the part of the brain, and some determining cause. The conclusions were—(1) that to be efficient leaders of the profession and teachers in

our public schools, hospital men should be thoroughly acquainted with diseases of women; (2) that whenever it is a question of hysteria, the state of menstruation should be carefully ascertained, and the sexual organs accurately examined when they present signs of disease; (3) that the best way to disperse the cloud that still obscures our knowledge of hysteria, catalepsy, and epilepsy, is to study the pathology of the ganglionic nervous system.

DR. CORNELIUS B. FOX read a paper "On the Estimation of Atmospheric Ozone by means of Aspirators and Acids." Having pointed out the great importance of estimating correctly the amount of ozone present in the air, if we would ascertain with certainty whether or not an excess or deficiency of this allotropic modification of oxygen is in any way connected with disease. He proceeded to comment on the chaotic and inexplicable condition in which all ozone records are involved. The mode of estimating ozone which has been hitherto generally adopted appears to be liable to the following sources of error:—I. Impurity of chemicals employed. II. Impurity of paper employed. III. Ozonometers faulty in construction. IV. Formation of the iodate of potash. V. Bleaching and fading of the coloured tests. (1) From formation of the iodate of potash; (2) from presence of true antozone in the air; (3) from volatilisation of the iodine set free, in consequence of (a) a rapid current of air, (b) an excess of moisture in the air, (c) a high temperature. VI. Changes in the force of the wind. Brodie and others consider Schonbein's antozone to be a myth, while some German savants have recently proved that it is simply the binoxide of hydrogen. Dr. Cornelius Fox believes in the existence of an antithetical state of the air, and describes both the atmospheric conditions under which it occurs, and its effect. This principle he names true antozone, to distinguish it from Schonbein's antozone, with which it has hitherto been erroneously identified. The various errors above enumerated, of which the formation of the iodate of potash is one of the greatest, are easily obviated. This colourless salt, into which much of the iodine set free by the ozone is often converted, he decomposed by the application to the tests of tartaric acid in the form of spray, so that the whole of the metalloid may be estimated. The error arising from the changes in the force of the wind is also avoided by the use of aspirators, by means of which a certain amount of air is made to pass over the tests at a certain velocity.

MR. DE BERDT HOVELL read a paper "On the Different Therapeutic Indications of Rheumatism and Neuralgia, together with some Remarks on Rheumatism as a sequela to Diphtheria." He said that both rheumatism and neuralgia are conditions of ill-health attendant on low or depressed nerve-power; both are highly susceptible of pain. In rheumatism the first object is to eliminate the lactic and other allied acids from the blood, and to reduce the excess of fibrine; in neuralgia, on the other hand, to supply the deficiencies of the blood, adopting the opinion of Dr. Bence Jones, that the absence of quino-iodine is the cause of malarious neuralgia. Similar treatment is called for in the neuralgia of exhausted nerve-power, in that of old age, and from organic disease. Both diseases are liable to aggravation from intestinal irritation, and neuralgia from carious teeth and other forms of diseased bone. In both diseases the susceptible condition of the nervous system calls for relief by some form of narcotic, &c. Acute rheumatism has frequently been observed to follow diphtheria, in which case it is important to ascertain that the urine is free from albumen before adopting the blistering treatment of Dr. Herbert Davies. Assuming that there is excess of fibrine in the blood in diphtheria as well as in rheumatism, cantharides has been found to check elimination by the kidneys, and so to aggravate the symptoms, especially the cardiac complications. In this class of case iodine and the iodide of potassium are specially advocated.

MR. CHRISTOPHER HEATH read a paper "On the Treatment of Stone in the Female Bladder," illustrated by three cases which had occurred in his own practice. The first case was in a patient, *æt.* thirty-two, who was subjected to lithotripsy, a stone weighing four drachms, composed of phosphates, with a nucleus of oxalate of lime, being removed in five sittings with complete success. The second case was in a married woman, aged forty-nine, in whom a large stone was readily felt per vaginam. Vaginal lithotomy was performed, and a stone of an ounce and a half, and measuring two inches by an inch and a half, was readily removed, the wound being closed immediately with six silver sutures passed through the entire thickness of both vaginal and vesical wall. The patient made a

rapid and complete recovery, without the formation of any fistulous opening. The third case was that of a child, *et. eleven*, in whom the urethra was rapidly dilated, and a small stone extracted, when there was found to be a much larger mass fixed to the bladder, which was removed with difficulty after being partly broken up, the whole mass weighing nine drachms. The child had incontinence for a few weeks after the operation, but eventually recovered complete control over the bladder. Mr. Heath briefly contrasted the three proceedings, maintaining that rapid dilatation of the urethra within certain limits was a perfectly harmless and most useful practice. He advocated lithotripsy for moderate-sized stones in the adult, but for large stones preferred vaginal lithotomy, with immediate closure of the wound, a proceeding which experience had proved to be remarkably successful.

MR. G. SOUTHAM, F.R.C.S. (of Manchester), read a paper "On Excision of the Tongue." He referred to the difficulty which surgeons frequently experienced in excising the entire organ, or even a large portion of it, for this affection. The safest mode of removal is that by the *écraseur*, but this instrument frequently fails to effect the purpose in consequence of the shape of the tongue, and the peculiar arrangement of the muscles, causing the chain of the *écraseur* to slip towards the diseased portion, in which it often becomes embedded before the operation is completed. Some cancerous deposit is therefore left, and, though it may not be in sufficient quantity to interfere with the healing of the wound, usually leads to an early return of the affection. To remedy this defect in the operation, Mr. Southam has had constructed a pair of forceps with a moveable hinge, which completely grasps the tongue at its root, and confines the action of the *écraseur* to the part where it is first applied. A case was described in which, with this instrument, and without making an opening in the floor of the mouth to pass the chain through, the tongue, of which the body was affected with cancer, was excised beyond the foramen cæcum and circumvallate papillæ, these structures being included in the separated portion.

DR. PROTHEROE SMITH read a paper on "Supplemental Mechanical Force during Parturition, regulated by a Dynamometer." After some allusion to the physiology of labour, and to the agents of force exercised in parturition—*viz.*, that of the voluntary and involuntary muscles—the author spoke of the injurious consequences when the normal balance of these powers was disturbed, specially marking the distinction between the capabilities of the uterus and of the trunkal muscles, to obviate which, as well as to subsidise the power at fault, he advocates the judicious employment of artificial force, according to certain rules, by means of his "obstetric pelvic band," which was described and exhibited. The peculiarity of this instrument is, that it forms, with the pelvis itself, as it were, a solid basis, which, by virtue of its immobility, allows the accoucheur easily to employ the required aid to assist and expedite expulsion, and so, by following the natural movements, manifestly to shorten the period of labour and to lessen its risks. This is regulated by a dynamometer, described and illustrated by a drawing. It is so constructed as to measure and record accurately the force employed, imitating the normal throes when wanting, especially by interrupted efforts like those constituting "the compound character" of such pains. In demonstration of this, Dr. Protheroe Smith narrated a case of labour in which such means were employed, with the result. In this, each pain, as well as the amount and duration of every artificial effort, is recorded, and some valuable calculations and observations were appended from the pen of Prof. Haughton, of Dublin, from which it appears that the force used in parturition is much greater than is generally supposed by obstetricians.

MR. S. M. BRADLEY, F.R.C.S. (of Manchester), read a paper "On the Unity of the Syphilitic Poison." Mr. Bradley commenced by showing that in order to demonstrate the unity of the syphilitic poison, it was necessary to produce a soft sore upon a virgin subject, by direct inoculation from a hard infecting sore; to produce, in other words, a sore indefinitely capable of auto-inoculation, but never followed by constitutional symptoms, from a sore which was (very generally) incapable of auto-inoculation, and which was followed by constitutional taint. He went on to say he had made numerous experiments to ascertain whether this interchange did or did not ever occur, and with the results which are now made public. His subjects were monkeys, kittens, and guinea-pigs; the virus he employed was obtained from cases of syphilis met with in private practice, in the Lock Hospital, and in the venereal wards of

the Manchester and Chorlton Workhouses. He obtained the matter for inoculation by scraping the surface of the sore prior to cicatrisation, with either a piece of glass or an ivory vaccination point. The great majority of the experiments gave negative results. In two instances, however (one in a guinea-pig, and one in a kitten), the inoculation was followed after the interval of two or three weeks by local thickening at the site of puncture, and later by the outbreak of constitutional symptoms. The guinea-pig died within a month from the commencement of thickening, with disorganisation of one eye, and extensive ulceration about the mouth and soft palate; in the kitten killed at the end of the eighth week were found gummata in the kidney and liver. Omitting failures, and the two cases of syphilis mentioned above, he obtained three successful results, the details of which were given. In these experiments, the initial lesion was never irritated by any application; Mr. Bradley merely used the secretion obtainable from the surface of the untreated sore. When the sore was irritated by savine, it was comparatively easy to procure abundant and as a rule, readily inoculable pus. He never succeeded in obtaining positive results with matter taken from a phagogenic sore, or with scraping the surface of one which was entirely void of all secretion. Mr. Bradley proceeded to draw a parallel between the two forms of syphilis and the evolution of the vegetable parasites, or epiphytes; alluding to the fact that all the fungi infecting the human subject are interchangeable, and mutually producible, and yet, as a clinical fact, it was well known that this interchange took place but very rarely,—it seemed probable to him, indeed, that the same causes which operated in this low region of the vegetable kingdom (*i.e.*, differences in the soil and in the age, &c., of the seed) were also the efficient causes in determining the character of the syphilitic sore, although we were not yet in a position to decide the precise force which each of these causes possesses.

DR. MORELL MACKENZIE read a paper entitled "Growths in the Larynx: the Comparative Advantages of Laryngoscopic Treatment, and Direct Incision into the Larynx." He stated that the relative advantages of these two methods must be considered in relation (1) to the quickness of cure, (2) completeness of removal and probability of recurrence, (3) danger to life, and (4) restoration of voice. From an experience of 100 cases treated, a month was estimated to be the average duration of laryngoscopic treatment. External treatment, on the other hand, required only a fortnight. As regards the second question, complete removal was able to be effected in 97 per cent. of the cases which underwent the full course of laryngoscopic treatment, and recurrence took place in about 7 per cent. In 28 cases of direct incision, collected from all sources, 10 died in a short time and in the remaining 18 the growth was incompletely removed in 3 cases, and recurrence took place in 3 cases, or, in other words, in 20 per cent. As regards danger to life, no death occurred in the laryngoscopic cases, whereas, of the 28 treated by external operation, 3 immediately terminated fatally, 6 died at the end of a few months, and 1 from an independent disease. With reference to restoration of function, perfect voice was regained in 77 per cent. of those who underwent laryngoscopic treatment, and a more or less serviceable voice was restored in 16 per cent. Of the eighteen patients who survived direct incision more than a few months, only 9\* completely recovered their voice, 4 had persistent hoarseness, and 6 permanent aphonia. Consideration of the above statistics establishes the permanent value of laryngoscopic methods of treatment, and justifies one in saying that extra-laryngeal treatment ought never to be adopted unless there be danger to life from suffocation or dysphagia.

DR. DAVY read a paper on "Jenner and his Teachings." It is designed to prove, from the early writings of Jenner, that we, of this day, have failed to practise vaccination after the manner, or rather in the light, of the first great teacher of the art; that we have ignored the preliminaries to which he attached very much importance; that Jenner doubted the virtue of the vaccine lymph after even five gradations, after its passage through but five persons or children successively, and that he thought it prudent after only five gradations, to seek other and fresh lymph from the cow or heifer.

DR. J. H. AVELING read a paper "On the value of Arsenic in Menorrhagia and Leucorrhœa." He believes that this

\* These cases are tabulated in the Thyrotomy table in the author's "Essay on Growths in the Larynx." In this table, however, the result of Case 27 is entered as "not stated," but since the publication of the volume Dr. S. Cohen has informed the author that the result was "complete restoration of voice."

remedy has not received from the profession the attention it deserves. Dr. Henry Hunt used it successfully in uterine disorders, and published his experience in 1838. Dr. Aveling has employed it in cases of menorrhagia for twelve years with great advantage. Besides improving nutrition, respiration, and secretion, he finds it to have a powerful decongestive action upon all mucous membranes. He administers small doses of arsenic either in solution or in granules, and continues them for weeks or months, as the necessities of the case may require. He believes the forms of menorrhagia and leucorrhœa most amenable to the arsenic treatment are those which have their origin in a hyperæmic condition of the uterus, which state the remedy cures by acting as a tonic and stimulant upon the vaso-motor nerves, causing the capillaries to contract and expel the superabundant blood.

DR. ALFRED MEADOWS read a paper "On the Treatment of Fibroid Tumours of the Uterus," in which he combated the notion that these growths can be in any way diminished in size, still less cured, by any known therapeutical agent. He advocated more frequent resort to surgical treatment, expressing his belief that much more might be done in many of these cases than has been hitherto. Even in the sub-peritoneal variety he thought that, in cases where much distension exists, abdominal section ought to be resorted to more frequently; while in the interstitial and submucous forms, it ought to be the rule in practice always to endeavour to assist Nature in her method of cure—viz., by expulsion. For this purpose three objects should be kept steadily in view. 1st. That all obstruction should be removed by freely dividing the cervix in several directions. 2nd. That the tumour should be separated from its attachments, not necessarily all at once, but by successive stages. 3rd. That as far as possible continuous uterine action should be maintained by the exhibition of ergot and other oxytotic agents.

DR. CLIFFORD ALBUTT read a paper on "The Lesions of Enteric Fever as an Occasional Cause of Permanent Injury to Nutrition," in which he drew attention to the convalescence from enteric fever, which is well known to be often so tedious; and he raised the question whether the specific lesions of that disease, affecting as they do the instruments of absorption, might not sometimes be the cause of permanent marasmus. In enteric fever the local mischief falls not only upon the patches of Peyer in the ileum, but spreads itself throughout the network of the mesentery. If a rat be fed upon tallow candles and then killed, the presence of the fat in great quantities in the mesenteric network and glands shows how active is that system in taking up this element of nutrition. Any disease, therefore, which interferes with this system, like enteric fever within it, or chronic peritonitis outside it, would have its visible effect in hindering the absorption of fat and in preventing the laying on of adipose tissue. These considerations occurred to the author in consequence of his advice being sought in several cases of marasmus, pure and simple, without local disease, without fever, and without adequate loss of appetite. In all of these a severe attack of enteric fever had preceded the marasmus. The patients, who were almost denuded of all adipose tissue, had, previous to the attack of enteria, been in good health. The only explanation which he could give of these cases was, that the fever had acted upon the fat-collecting system in the way already pointed out.

DR. WYNN WILLIAMS read a paper "On the Treatment of Cancer of the Neck of the Uterus and Allied Structures by the Injection and Application of Bromine." He stated that the eight cases published in the last volume of the *Obstetrical Transactions* still continued well. And gave the history and successful treatment of a case of medullary carcinoma of the uterus in the state of disintegration and ulceration by this method. He also gave the particulars of a case of epithelioma of the lower lip which had been previously removed by operation. On its return two injections of bromine, caused the entire and, so far, permanent removal of the disease.

DR. BRAXTON HICKS read a paper "On a Rare Form of Hæmorrhage." After quoting the remarks of Dr. Blundell on a form of concealed hæmorrhage, caused by the falling down of the membrane, and consequently the retention of blood within the uterus, he brought forward three cases in which, the membranes remaining attached all round the lower portion of the uterus, and blood being effused between the upper part of the uterus and the membranes and margin of

placenta, the membranes and a portion of the placenta were inverted so as ultimately to be driven through the os into the vagina some distance, imitating the bag of membranes in a twin-case after the birth of the first child. The uterus in the meantime became distended with blood, and serious symptoms arose without any sign externally. The treatment was pointed out, and some short remarks made on the mode of expulsion of the placenta.

DR. BRAXTON HICKS also described four cases of Acute and two of Chronic Inversion of the Uterus, following each case by remarks on the causation, prevention, and treatment. He showed some apparatus he had devised for the restoration of chronic inversion, consisting first of India-rubber pessaries, and then of an apparatus to keep up constant pressure on the fundus, a simple kind of which he had found successful.

DR. BARNES exhibited an enlarged drawing, taken from a specimen recently put up at St. Thomas's Hospital, which showed, with an accuracy probably unique, the anatomical characters and relations of Hypertrophic Elongation of the Cervix Uteri. The entire length of the uterus was seven inches. The two lips of the os uteri were much hypertrophied, somewhat everted, and formed a large mass external to the vulva. The whole vagina was everted to clothe the protruded mass. The retro-uterine pouch of the perineum was extended so as to be outside the vulva. The value of the preparation was great, as giving a typical illustration of a not uncommon affection, the relation of all the parts being accurately preserved.

FOREIGN DECORATIONS.

WE learn that the Foreign Office is about to re-examine the regulations having reference to the acceptance of foreign decorations by British subjects, with the ostensible object of permitting those of our countrymen, and especially members of the Medical Profession, who distinguished themselves during the late Franco-German war, to receive and wear decorations conferred upon them by the respective governments of the belligerents. Considering the important rôle which ambulances under the convention of Geneva played in that war, and are certain to play in future European wars, it is both politic and just on the part of our Government to encourage all Englishmen who, with due authority, follow armies in the field and give help and succour to the wounded, often,

as must necessarily be the case, at much risk and danger to their own lives and limbs; but in regard to surgeons actually in the British Army, who have been, or may be similarly employed, it seems to us that the regulations as they stand are not only amply sufficient, but that under them, there are several Medical officers now in possession of foreign *orders* received for services performed in the Crimea.

Let us examine this matter for a little. The regulations respecting Foreign Orders are precisely word for word the same to-day as they were in August, 1856. According to the *Gazette*, dated Whitehall, 2nd of that month:—"The Queen has been pleased to grant to the undermentioned officers and men, Her Majesty's royal license and permission, that they may accept and wear the insignia of the several classes of the Imperial Order of the Legion of Honour attached to their respective names, which His Majesty, the Emperor of the French, hath been pleased to confer upon them as a mark of His Imperial Majesty's approbation of their distinguished service before the enemy during the late war, and that they may enjoy all the rights and privileges thereunto belonging." Then follow a long list of officers of the navy, the army, and marines; Medical officers being enumerated with those of the "*combatant*" branches, according to their relative rank. On that occasion five Medical officers of the royal navy and fourteen of the army, obtained permission to accept and wear the Cross of the Legion of Honour, for "*distinguished service*" before the enemy; the names of the recipients being chronicled for reference at pages 183 to 191 of the "Army List," for September of that year. We desire to be particular in regard to this point, as surely the same kind of services by army surgeons, which in 1856 were considered *distinguished* for the purposes of meriting the distinction of the Legion of Honour, must be so still in 1871. On the one occasion as on the other, professional service to and in the interest of the wounded is clearly what is meant, and, if we read the regulations attentively, it becomes equally clear that their terms are not restricted to one particular kind of service to the exclusion of all others; but that, inasmuch, as all branches of an army are concerned in bringing about a general result, so the regulations as then *acted* upon, and still in force, embrace all. Thus among the recipients belonging to the navy and marines, we find the names of "executive" officers, as also we do those of masters, secretaries, medical officers, engineers, paymasters, warrant officers, non-commissioned officers, and privates; among those of the army there are, besides *combatants*, officers of the medical and commissariat departments, besides non-commissioned officers, and not a few private soldiers.

How then comes it, that the two surgeons of the British Army, whose names have of late been somewhat prominently brought forward in connection with ambulances during the Prussian siege of Paris, are considered by the Foreign Office as being outside the regulations referred to? We can only look upon it as the result of wilful or inadvertent misconception. It is true that neither were Deputy Inspector-General Gordon, C.B., nor Surgeon-Major Wyatt sent from this country for the purpose of attending the wounded of the belligerents; but, on the contrary, that they were dispatched by the War Office in the capacity of commissioners to the French Army, for the purpose of reporting upon the arrangements made or the disposal of the wounded as well as for their in-

dividual treatment. [The chances of war led to their being among the besieged in Paris, and their own tenacity of purpose induced them to remain at their posts, to take the risks of doing so in the absence of orders to depart, rather than exercise that *discretion* which led other British officials to quit the besieged city before the real difficulties and dangers of the siege began. But our commissioners, very properly we think, instead of simply remaining as indifferent spectators among the besieged, endeavoured, and as it now appears successfully to afford what help was in their power; they accordingly joined some of the ambulances, and on the occasion of the great sorties and battles, gave active assistance to the wounded on the field, being for these services rewarded with the Cross of the Legion of Honour. Surely when we bear in mind that those services were rendered throughout one hundred and thirty days, the last twenty-one under continued bombardment; and that the battles at which they were present in the performance of their merciful task—namely, Malmaison, Champigny, Bourget, and Montretout, were among the most severely contested and deadly of all that were fought in the war, it cannot be denied that their services were literally and undeniably before the enemy as well as on the field.

#### CHOLERA.

THE protest we last week made against the distribution of official documents to some papers, and the withholding of them from others, has received an important justification in the notices issued in reference to cholera!

Of course we are glad to see precautions urged upon the public, and have, therefore, witnessed with pleasure the publicity accorded to the Privy Council's injunctions. We repeat, however, our statement that the medical journals should be supplied with copies of all official documents relating to public health or sanitation, not one medical journal but all; and, we repeat our question, whether it is with the knowledge of "the Lords of Her Majesty's most Honourable Privy Council," that one journal is supplied with early copies of the Blue Books and other documents of the Medical Department, while another is not supplied at all?

Having, again, put our question—in a still more prominent position—we wait the reply, and pass on to notice the precautions against cholera urged by the Department. As a few imported cases are sure to occur, it is encouraging to the local authorities of our ports to be assured that they are not likely to spread where proper sanitary arrangements exist. In order to enable such local authorities to best defend themselves, a sketch of the mode in which the invasion usually takes place is appended, which opens with the assurance—very agreeable to the general public and fully supported by other communications in our journal—that the disease is but slightly contagious. The fourth section of the paper before us reads thus;

4. Happily for mankind cholera is so little contagious, in the sense in which small-pox and scarlatina are commonly called contagious, that, if reasonable care be taken where it is present, there is scarcely any risk that the disease will spread to persons who nurse and otherwise closely attend upon the sick. But cholera has a certain peculiar infectiveness of its own, which, where local conditions assist, can operate with terrible force, and at considerable distances from the sick. It is characteristic of cholera, not only of the disease in its developed and

alarming form, but equally of the slightest diarrhoea which the epidemic influence can cause, that all matters which the patient discharges from his stomach and bowels are infective, and that, if they be left without disinfection after they are discharged, their infectiveness during some days gradually grows stronger and stronger. Probably, under ordinary circumstances, the patient has no power of infecting other persons except by means of these discharges; nor any power of infecting even by them, except in so far as particles of them are enabled to taint the food, water, or air which people consume. Thus, when a case of cholera is imported into any place, the disease is not likely to spread, unless in proportion as it finds, locally open to it, certain facilities for spreading by indirect infection. In order rightly to appreciate what these facilities must be, the following considerations have to be borne in mind:—First, that any choleraic discharge cast without previous thorough disinfection into any cesspool or drain, or other depository or conduit of filth, infects the excremental matters with which it there mingles, and probably to some extent the effluvia which those matters evolve; secondly, that the effective power of choleraic discharges attaches to whatever bedding, clothing, towels, and like things have been imbued with them, and renders these things, if not thoroughly disinfected, as capable of spreading the disease in places to which they are sent (for washing or other purposes) as, in like circumstances, the cholera patient himself would be; thirdly, that if by leakage or soakage from cesspools or drains, or through reckless casting out of slops and wash-water, any taint, however small, of the infective material gets access to wells or other sources of drinking water, it imparts to enormous volumes of water the power of propagating the disease. When due regard is had to these possibilities of indirect infection, there will be no difficulty in understanding that even a single case of cholera, perhaps of the slightest degree, and, perhaps, quite unsuspected in its neighbourhood may, if local circumstances co-operate, exert a terribly infective power on considerable masses of population.

Obvious as are the precautions that follow from these facts, it is admitted that we cannot be sure that they are always taken. We cannot enforce universal disinfection where cases occur. Mild cases may be overlooked, their nature not recognised.

Our defence is, therefore, partial, unless we can ensure that cholera-contagium, even if not disinfected, shall not find access to our water or, in any other way, be able to act on the population.

The dangers are discovered in Section 6:—

6. The dangers which have to be guarded against as favouring the spread of cholera-contagium are particularly two. First, and above all there is the danger of water supplies which are in any (even the slightest) degree tainted by house refuse or other like kinds of filth as where there is outflow, leakage, or filtration from sewers, house drains, privies, cesspools, foul ditches, or the like into streams, springs, wells, or reservoirs from which the supply of water is drawn, or into the soil in which the wells are situate—a danger which may exist on a small scale (but, perhaps, often repeated in the same district) at the pump or dip-well of a private house, or on a large and even vast scale in the source of supply of public waterworks. And, secondly, there is the danger of breathing air which is foul with effluvia from the same sorts of impurity. Information as to the high degree in which these two dangers affect the public health in ordinary times, and as to the special importance which attaches to them at times when any diarrhoeal infection is likely to be introduced, has now for so many years been before the public, that the improved systems of refuse-removal and water supply by which the dangers are permanently obviated for large populations, and also the minor structural improvements by which separate households are

secured against the dangers, ought long ago to have come into universal use. So far, however, as this wiser course has not been adopted, temporary security must, as far as practicable, be sought in measures of a palliative kind. (a) Immediate and searching examination of sources of water supply should be made in all cases where the source is in any degree open to the suspicion of impurity, and the water both from private and public sources should be examined. Where pollution is discovered, everything practicable should be done to prevent the pollution from continuing, or, if this object cannot be attained, to prevent the water from being drunk. (b) Simultaneously, there should be immediate thorough removal of every sort of house-refuse and other filth which has accumulated in neglected places; future accumulations of the same sort should be prevented; attention should be given to all defects of house-drains and sinks through which offensive smells are let into houses; thorough washing and lime-washing of uncleanly premises, especially of such as are densely occupied, should be practised again and again. (c) Disinfection should be very freely and very frequently employed in and round about houses, wherever there are receptacles or conduits of filth, wherever there is filth-sodden porous earth, wherever anything else, in or under or about the house tends to make the atmosphere foul. In the absence of permanent safeguards no approach to security can be got without incessant cleansing and disinfections, or without extreme and constant vigilance against every possible contamination of drinking water. (For detailed advice on disinfection, see the Office Memorandum on that subject.)

The Memorandum then refers to the responsible authorities in each case, and shows that as they are elected by the ratepayers, these are able to enforce their will. It is then wisely added that expense incurred for the purpose of protecting a district from the invasion of cholera, can in no case be wasted, as the very conditions that enable cholera to spread, in the absence of that disease, give rise to others.

It is to be hoped this lesson will be taken to heart by local constituencies. The present panic about cholera will then be the means of diminishing many other diseases.

The precautions taken in all directions will, it may be hoped, abate the violence if they do not prevent the occurrence of the threatened epidemic. We deprecate strongly any alarming statements, though it is useless to disguise our dangers. Dr. Edmunds says his case was of the true Asiatic type, and Dr. Buchanan recommended the destruction of the bedding. Similar alarming statements have been made in other divisions. We continue our narrative of the progress of the disease.

From the beginning of the year, as we have shown, it has prevailed at St. Petersburg. In the middle of June the epidemic broke out in other parts of Russia, chiefly in the Governments of Wilna, Riazan, Tambov, Pskov, Olonetz, and Novgorod. Later, becoming more severe at Moscow, it made its appearance in some of the central Governments, and became more virulent in the Governments of Tambov, Jaroslav, Vladimir, and Wilna. Still later Nijni-Novgorod, Livonia, Vologda, Kostroma, Kasan, Tver, Tula, Smolensk, Mobilev, and Saratov, and in the Governments on the Vistula, especially in that of Souwalki, were invaded. Physicians, surgeons, and medical students have been sent to the Governments of Tambov, Jaroslav, Novgorod, Vladimir, and Olonetz to assist in the treatment of cholera patients. At present, with the exception of Moscow and some districts in the Government of Tambov, particularly in those of Borisoglebsk and Kirsanov, and in some districts of the

Government of Vladimir, the epidemic has already considerably diminished in intensity, but fears are entertained of a revival, especially at Nijni. Later advices state that in the Russian Province of Suwalki cholera is on the decrease. From the 20th to the 27th of July there were 238 fresh cases. The whole number of cases that had occurred was 443, and of the persons attacked 83 had died, while 190 had recovered.

## PERSIA.

The *Levant Herald* of the 9th inst. states that on the Saturday preceding a telegram had been received by the Galata Board of Health, from Tabreez, reporting the rapid spread of cholera in that city. The deaths from the epidemic had averaged 200 a day, and the inhabitants were flying in thousands towards Corumiah and Khoi. It is also said that famine is very severe in those districts. Cholera has broken out at Lingah, and the mail steamers have not been calling there. It prevails at Bahrein, on the Arab littoral, and in the Turkish camp at Khatif.

## GERMANY.

According to the official register, the deaths by cholera for the week ending the 11th inst., at Königsberg, numbered 44, 15 being children under eleven years of age. The disease is generally attributable to want of food and of cleanliness. Hardly any of the middle or upper classes have been attacked. On Saturday week 40 persons were attacked there by cholera, 19 deaths occurring from the epidemic on the same day; on Sunday 38 were seized, and 16 died. At Neufahrwassen some cases of cholera had occurred on board ship on the 14th, and at Königsberg 62 cases, and there were 22 deaths.

## Notes on Current Topics.

### Examination Reform at the Irish College of Surgeons.

THE Council of the Royal College of Surgeons in Ireland have at length, we learn, finally adopted the scheme of Education and Examination which they laid before the Fellows last June, and which we published *in extenso* in our issue of May 31.

The Sessional Examinations essential for the granting of the Letters Testimonial are to be three in number, instead of two, as at present, and must be passed by the candidate within the following periods:—

- (a.) The Primary Examination, at any examination after the termination of the Second Summer Session.
- (b.) The Secondary, at any examination after the termination of the Third Summer Session.
- (c.) The Pass or Practical Examination, at any examination after the termination of the Fourth Summer Session.

Each examination will occupy two days, of which the first is to be devoted, in the Primary and Secondary Examinations, to the writing of answers to printed questions; and in the Pass Examination, to clinical examination and operative surgery; and in the second day, in all cases, to *viva voce*.

For the written examination four hours are to be allowed to candidates on the first day,—two in the forenoon and two in the afternoon; but candidates may retire from the hall when they shall have completed their answers, and handed their papers to the Examiner.

The *Viva Voce* Examinations commence on the day following the written examinations, and are continued from day to day until all candidates have been examined. Each candidate is examined for a quarter of an hour by each of the four examiners.

The Sessional Examinations commence on the second Tuesday in April and July, and the first Tuesday in December. The Primary and Secondary written examinations take place on the first day; and the *Viva Voce* Examination first of the Primary and afterwards of the Secondary class, are continued from day to day in the alphabetical order of candidates' names.

The candidates are to assemble in one of the rooms of the College, having been previously informed of the hour at which they are to attend by means of a note forwarded to their addresses through the post, and that at the conclusion of the examination the result is communicated to them in the same manner.

For the Primary Examination: The subjects for this examination are—

- a. Anatomy (bones, muscles, ligaments, chest, abdomen, urinary and genital organs).
- b. Physiology of digestion and of absorption.
- c. Chemistry (chemistry and physics, as applied to pharmacy and medicine).
- d. *Materia Medica* and Medical Botany (not including prescriptions or pharmacy).
- e. Principles of Surgery (inflammation and its consequences).

For this examination the candidate is required to produce the following certificates:—

- (a) Practical Anatomy, with demonstrations and dissections, two winter sessions; (b) Physiology, one course; (c) Theoretical Chemistry, one course; (d) Practical Chemistry, one course; (e) *Materia Medica*, one course; (f) Botany, one course; (g) Surgery, one course; (h) Eighteen months' hospital attendance.

Secondary Examination: The subjects for this examination are—

- a. Anatomy (regional and surgical).
- b. Physiology and Histology.
- c. Surgery, general and theoretical.
- d. Medicine, practical.

The description of anatomical specimens, and of microscopic histological preparations form part of the written examination.

Also the candidate is required to produce the following certificates, in addition to those required for the Primary Examination:—

- (a) Physiology, two courses; (b) Practical Anatomy, one course; (c) Surgery, one course; (d) Practice of Medicine, one course; (e) Medical Jurisprudence, one course; (f) Nine month's Hospital attendance.

Final or Pass Examination: The subjects of this examination are—

- a. Clinical Examination.
- b. Surgical Operations.
- c. Surgical Appliances.
- d. Prescriptions.
- e. Medical Jurisprudence.

#### *Clinical Examinations.*

The forenoon of the first day of the Pass Examination is devoted to Clinical Examination, and the afternoon to Operative Surgery.

The candidates attend at the College half an hour before

the time fixed for the Clinical Examination, and that a certain number of candidates, previously selected by lot to attend each hospital, are then informed as to the hospital at which they are to be examined, and proceed thither at once to meet their examiner.

On the afternoon of the same day the examinations in Operative Surgery and Surgical Appliances take place, and that not less than two operations and three surgical appliances form the subjects of examination for each candidate.

The second day of the Pass Examinations is devoted to the writing of prescriptions and to medical jurisprudence; and each candidate is examined for one hour.

#### *Midwifery Examination.*

An examination in Midwifery is held at the same time as the Pass Examination; the passing of which shall, however, not be compulsory on candidates for Letters Testimonial. Any candidate presenting himself for examination in that subject shall, if passed, receive the Midwifery Diploma without extra fee.

The candidate is required to produce the following certificates, in addition to those required for his two previous examinations:—(a) Midwifery, one course; (b) Surgery, one course.

#### *Marks to be Given.*

The maximum number of marks which it shall be possible for any candidate to receive at any examination shall be fixed at 40; he shall not be allowed to pass unless his aggregate marks amount to 25; that no examiner shall give a higher number than 10.

#### *Fees to be paid by the Candidate in respect of each Examination.*

1. That each registered pupil shall be admitted to the Primary Examinations on payment of a fee of £5 5s.
2. That the fees for the Second and Final Examination shall be £5 5s. each, and that a fee of £5 5s. shall be paid, in addition, previous to the Final Examination for the Diploma.
3. Any rejected candidate seeking re-examination shall pay an additional fee for such examination of £2 2s.
4. That no fee shall be charged for the Midwifery Diploma to any candidate who may pass in Midwifery at his Final Examination, or the next following periodical examination.

We are informed, and receive the information with much regret, that the Council have decided to leave this much needed reform of the admittedly defective examination system to the option of the student. Examinations under the old system will still be continued, and the improved and more liberal method will not be obligatory upon any student, except those who commence their studies henceforth. This compromise is so obviously impracticable and undesirable that we are assured it must fall to the ground in a few months, and the reformed examination be substituted in all cases for the present inefficient test.

DR. POLECK calls attention, in the *Polytechnisches Journal von Dingler* for May, to a peculiar change which takes place in flour kept in casks. The gluten of the flour loses its capability of being converted into a good dough, and acquires a peculiar musty smell. The cause of this is referred to the absence of air: therefore the remedy is obvious.

## **Dirt, Poverty, and Drunkenness amongst the Working Classes.**

IN an interview of the Commissioners who conducted the recent inquiry into the mortality of Liverpool with the Land and House Owners' Association, some of the members of the association expressed an opinion that the habits of the people were much dirtier than before 1847. At that time the cleanly poor insisted on a dirty person removing from a court, and the owners were obliged to compel them to leave for fear of losing their other tenants; but now that sense of cleanliness seemed lost even by the English, who were formerly very clean. This increasing dirtiness was attributed, to a great extent, to increasing poverty and intemperance; but, in addition to these, other causes were assigned. The epidemic of relapsing fever probably led to the enforced cleaning of the houses; but, in spite of this enforced cleanliness, nothing could exceed the dirt of the people, and the fetid condition of the atmosphere at night. How human beings could tolerate such a state of things would be incredible if they did not know the deadening influence of custom. With regard to the people and furniture of these houses, the Commissioners were not at all prepared either for the wretched appearance of the people or for the aspect of poverty disclosed. They could not have believed that in any town in this country that they could have gone into room after room, and house after house, and have found in so many cases literally almost nothing but the bare walls, a heap of straw covered by dirty rags, and possibly the remains of a broken chair or table. In some houses there were no cooking utensils of any kind, or only an old saucepan. Another point was that many people seemed to have no change of clothes. Inquiry from some people extracted the fact that they occasionally washed their hands and faces at the tap, but they seldom remove their clothes. The inquiry of the Commissioners led them to the conclusion that intemperance played a very large part in bringing about the poverty—with all its attendant evils—that existed. After giving instances with which they had met of constant employment and good wages associated with utter poverty, the Commissioners state that instances of this kind so frequently occur in all the poor districts of Liverpool that they questioned whether 20 per cent. of the labouring class in these streets were leading lives of ordinary restraint and decency.

### **Effect of the Weather on Infant Mortality.**

THE Registrar-General's Report gives some interesting facts on this subject:—

“The weather during the second quarter of this year was unreasonably cold, and the continuance of north-east wind was unusually long even for an English spring; indeed it may be said to have prevailed throughout the entire quarter, except between the 12th and 29th of April. Excepting that of 1860, last June was the coldest on record since 1821. Of the total deaths in England and Wales last quarter, 22 per cent. were of infants under one year of age, and 23 per cent. of persons aged 60 years and upwards, leaving 55 per cent. as the proportion of children and adults aged between one and 60 years. The 7,000 deaths from small-pox, which is only to slight extent fatal among persons aged 60 years and upwards, somewhat disturbs these proportions, and especially makes the proportion of deaths of elderly persons to appear smaller during last quarter than was actually the case. In the 17 largest English towns, of the total deaths

registered in the three months ending June, 23 per cent. were of infants under one year of age, while the proportion of deaths of persons aged 60 years and upwards was only 17 per cent. ; the low percentage of deaths of elderly persons in great measure was due to the excess of deaths of children and adults from small-pox. In the several towns the proportion of deaths of persons aged 60 years and upwards ranged from 12 and 13 per cent. in Salford and Sunderland to 27 and 29 in Nottingham and Norwich. To each hundred births registered in these 17 large towns last quarter an average of 16 deaths of infants under one year of age was registered. Infant mortality, measured in this manner, ranged in the several towns from 11 and 12 in Nottingham and Wolverhampton to 20.9 and 22.7 in Newcastle and Liverpool."

### Physiological Experimentation.

A committee consisting of ten individuals having been appointed at the last meeting of the British Association, held at Liverpool, to consider the subject of physiological experimentation, in accordance with a resolution of the General Committee, the following report was drawn up and signed by seven members of the committee:—

"1. No experiment which can be performed under the influence of an anæsthetic ought to be done without it. 2. No painful experiment is justifiable for the mere purpose of illustrating a law or fact already demonstrated. In other words, experimentation without the employment of anæsthetics is not a fitting exhibition for teaching purposes. 3. Whenever, for the investigation of new truth, it is necessary to make a painful experiment, every effort should be made to ensure success in order that the suffering inflicted may not be wasted. For this reason no painful experiment ought to be performed by an unskilled person with insufficient instruments and assistance, or in places not suitable for the purpose—that is to say, anywhere except in physiological and pathological laboratories under proper regulations. 4. In the scientific preparation for veterinary practice, operations ought not to be performed upon living animals for the mere purpose of obtaining greater operative dexterity. Signed by M. A. Thomson, Oxford; John H. Balfour and Arthur Gamgee, Edinburgh; G. M. Humphrey, Cambridge; William Flower, Royal College of Surgeons, London; J. B. Sanderson, London; George Rolleston, secretary, Oxford."

### Gelatine as a Vehicle for Powerful Medicines.

DR. T. HUSEMAN (*Centralblatt Med. Wiss.*, No. 157) gives an account of the method of Prof. A. Almen, of Upsala, for the administration of medicines by means of the gelatinæ medicatæ in lamellis. This method which has been extensively used in Sweden, renders the administration of powerful medicines easy and exact. Glue (6 grammes) is dissolved in warm water (230-260 cent.) and then the medicine added. The solution is poured upon a plate of glass to solidify and dry. The stiffened mass, of the thickness of paper, is divided into squares, each of which contains a certain dose. A slight addition of glycerine serves to make the otherwise brittle gelatinæ tough, and flexible as paper. Too much glycerine makes the gelatinæ soft and too readily moist. With insoluble drugs it is necessary, that the medicine be added to the solution of glue in a thick emulsion; gum-acacia is to be preferred to gum-tragacanth. The gelatinæ must not be placed dry upon the tongue, but moistened and swallowed with a gulp of water. The chief drugs thus used by Prof. Almen are: Gelatinæ morphii acetici, tartarized antimony, acetate of lead, sulphate of copper, extract. opii, opii levantici, extract.

belladonnæ, extract. colocynth comp., hydrarg. chlorat. mitis, pulv. rad. ipecac., infusion ipecac., pulv. fol. digitalis, infusion digitalis, camphoræ. The gelatinæ atropini and physostigmatis, for local application to the eye, have proved useful, but the gelatinæ sinapis and cantharidum for external application to the skin have not yet been thoroughly tried.

### The Treatment of the Itch.

UPON the suggestion of Froellich, Dr. A. Monti experimented upon the action of copaiba-balsam on the itch of children. The freshly-captured itch insect dies in from two to three hours when placed in copaiba-balsam. The balsam produces on the skin redness and a sensation of burning; after half an hour these symptoms pass away and with them the troublesome itching. After three or four inunctions, spread over one or two days, the efflorescence of the skin grows pale. Scabies nodosa, without eczema, is the most readily healed—the balsam has no influence upon eczema or upon pustules. The balsam of copaiba is cheaper than that of Peru, it does not stain the linen, and says Monti, has a more pleasant smell (!!) The treatment lasts from two to twelve days. Carbolic acid, in solution (one to two drachms to one pound of water) or in the form of salve, ʒj. to ʒiv. unguent simpl. was also tried. In scabies pustularis, poultices are used instead of the initiatory washing or baths. The redness and burning of the skin caused by the carbolic acid soon pass off. Six to nine inunctions, in the space of two to four days are required; if eczema is present the treatment lasts longer. This method is much to be recommended for children.—In the *Centralblatt f. d. Med. Wiss.*, for April, 1871.

### Subcutaneous Injection of Stimulating Substances.

IN a patient *in articulo mortis* from pneumonia, Dr. Rhode injected, subcutaneously, acid. benzoic. in spir. vini rect. four times in intervals of a quarter of an hour, so that in all 0.5 gramme acid. benzoic. were employed. After the second injection an effort of coughing ensued, the pulse increased in strength, and after the lapse of three hours the patient was enabled to take nourishment and wine and he recovered. Dr. Rhode has also employed a combination of camphor and acid. benzoic. in the following form: camphor, 1.0, acid. benzoic., 1.5, spir. vini. rect., 12.0. On account of the intense pain caused by the injection, it is only admissible where the patient is unable to swallow medicines, or when absorption is suspended.

### The Anatomy of the Spleen.

THE recent investigations of Dr. E. Kyber, on the minute anatomy of the spleen, are detailed in *Archiv. f. Mikros. Anat.* vi., 540-580, from which it appears that Billroth, Kölliker, and others ascribe to the spleen a vascular system which is closed on all sides, while W. Müller asserts that the connection between the capillaries which proceed from the resolution of the arteries occurring in the interior of the Malpighian corpuscles, and the veins, is restored by means of a system of intermediate blood-channels, of hollow spaces, which, without possessing any proper walls, are merely bounded by the cells and fibres of the inter-vascular tissue of the pulp.

Kölliker rejects the latter view, and ranges himself on the side of the first named investigators. The capillary ends of the arteries open directly, terminal or parietal, at

right or acute angles in the commencement of the veins. It is sometimes possible to fill the ends of the arterial vessels with the venous injection material, without the occurrence of extravasation. In injecting the arteries, the material readily passes from the arteries into the veins without the occurrence of a rupture of the walls, but it is not possible thus to fill large veins. The blood moves in the spleen only in closed channels; any passage of the corpuscular element from them into the tissues is always to be regarded as a pathological occurrence. The study of the so-called diffused amyloid degeneration of the spleen leads to the same conclusion. We can follow step by step the amyloid transformation of the parenchyma of the spleen without gaining a view in any of the stages of degeneration of the intermediate blood-channels described by Muller. This same degeneration of the spleen proves further, beyond any doubt, that the parenchyma of the spleen and the lymphatic sheaths of the vessels are not to be regarded as belonging together (Schweiger, Seidel), but are two distinct tissues (Billroth, Frey), in that each by itself, as in the sago-spleen, or as in the diffused degeneration, is attacked by different and to itself peculiar kinds of amyloid degeneration.

Kölliker effected the injection of the deep lymphatic vessels, that is, those discovered by Tomsa, as penetrating the entire organ, only in the spleen of the horse.

#### Patent Medicines in the United States.

THE *Chemist and Druggist* notices in its last issue an American trade catalogue, which contains over eighty pages, and gives a good idea of how energetically the Americans force this business. In "balsams" there are between forty and fifty proprietary names. No less than fifty-seven lines are devoted to "bitters." Nine kinds of brandies are included.

#### Apparatus for Dividing Powders.

AN American has invented an apparatus for proportioning and dividing powders. The invention consists of a board or plate of any kind or substance best suited for the purpose, having any required number of holes or pockets of uniform size and shape made through or in it, and each hole provided with a moveable bottom or piston arranged for shifting quickly, to vary the depth of the pocket, all the said bottoms or pistons being arranged so as to move equally in relation to the plate or holes therein. In using this instrument the mass of powder is placed on the table, and scraped over the holes so as to fill as many as the number of divisions required. The pistons are then raised to the level with the table, and the powder raised up in separate piles, to be scraped away.

#### Fraudulent Substitutions.

THE *American Journal of Pharmacy* for July says it has been informed that the fraudulent sale of muriate of cinchonia for sulphate of quinia exposed in its column has not ceased, but that, on the contrary, it is being sold quite largely, under the label of Pelletier, Delondre et Levaillant. It also states that sulphate of quinia is being sold for sulphate of morphia, and labelled as the make of Atkinson, of London.

#### Warnings of Cholera.

THE *Pall Mall Gazette* points out that some years ago Dr. Guy, professor of hygiene at King's College, London, drew attention to the fact that an outbreak of cholera was often preceded by the milder epidemic—influenza. The prevalence of the latter malady during the past winter and spring may seem to have been amply accounted for by the exceptional severity of those seasons, but nevertheless it may have its significance and warning. Both epidemics have this in common—that they progress in fatality to a certain point, and then gradually subside. There is certainly no resemblance between the present year and the year 1854, when the last cholera epidemic prevailed. In 1854 the drought was general, and although during the month of July there was much rain, yet the year was altogether a very dry one, and from the commencement of March extraordinarily warm. The progress of the malady when once it reached our shores (for there can be no doubt that it was imported) was very remarkable. Till the middle of July hardly a case was known, but before the end of that month the deaths had risen from five to 133. The disease went on increasing week by week, till, in the eighth week, it reached its maximum mortality of 2,050. It took thirteen weeks to fall again to five.

#### Fever in Milk.

It seems to have been established beyond reasonable doubt that the recent outbreak of fever in St. Andrews has had its principal origin in the transmission of the disease by milk. The infection was actually spread through the town by the medium of the daily allowance of milk from one particular dairy. The mistress of the dairy had the fever, and milked the cows through part of her indisposition; then the cow-boy took it, and, not being ill enough or rich enough to lay by, continued at his work the whole time, and went on with his milking with his fevered and peeling hands. The consequence was that in every house to which this milk was sent scarlet fever broke out. The revelation of such a remarkable train of events makes us shudder at the thought of what we may be drinking when we drop rich cream into our tea, or set bowls of new milk before our children, in blind belief that it is the best diet they can have. It seems almost past belief that any woman with the infection of fever upon her could go about her dairy work, or suffer a boy to pursue his duties through all the phases of such a disease as scarlet fever, however mild. But the facts are substantiated by Dr. Bell, and henceforth we must recognise the existence of a more subtle means of poison propagation than we have yet known of.

#### Health of Foreign Cities.

OF the health of the Continental watering-places no returns appear to be published, but the co-operation of the municipal and other authorities of most of the large cities enables our Registrar-General to report from time to time on their condition of health. He says that this is of infinite value to intending visitors, as at the present time, with small-pox so generally prevalent and a possible visitation of cholera, it is important to be able to refer to reliable figures, instead of depending upon desultory and often exaggerated reports, sometimes spread from interested motives. Unfortunately the interruption in the continuity

of the returns from Paris and Berlin caused by the late war did not cease until after April, and we are unable to present complete quarterly returns for either of those cities. Paris has in the past six weeks presented a remarkably clean bill of health, while Berlin has been suffering from epidemics of small-pox and diarrhoea. Brussels also suffered from small-pox during the quarter, and showed an annual death-rate from this disease equal to 7 per 1,000.

The epidemic of small-pox in Holland showed signs of decline in June, but in the first five months of this year in the principal towns of South Holland, 728, 988, 1,218, 1,209, and 958 (in all 5,101 deaths) were respectively referred to this disease. Among the towns which suffered most severely were Rotterdam, The Hague, Leyden, Delft and Delftshaven, Charlois, Kralingen, and Waddinsveen.

In New York the death-rate during last quarter was 28 per 1,000, and in Bombay only 20; small-pox was prevalent in both these cities, and was fatal to the extent respectively of 1 and 3 per 1,000 annually of the population.

Weekly returns are now received from both Rome and Florence, and, if the series be unbroken, a summary will appear in the next Quarterly Return. No returns have recently been received from Vienna, but it is to be hoped that they will soon be resumed; and also that before long St. Petersburg will take its place among the other principal Continental cities by furnishing similar contributions to international vital statistics.

### Health of Sea-side Towns.

JUST now few subjects are of more importance than this, and it is a matter of congratulation to find that in the mortality returns, as at this season of the year people leave towns in search of health, a special report is supplied of the state of the forty-seven principal English watering-places, which it is gratifying to find are unusually healthy. They are divided into two classes—thirty-eight on the pleasantest parts of the sea-side, and nine inland; and the report says:

“Many English people naturally resort to foreign countries to pass their holidays for various valid reasons; but neither they nor any others in search of health can find healthier places than in England. Germany has her Rhine, great as the river of a small continent can be, but without the grandeur, variety, and freshness of the sea encircling the English coast; here the green grass and foliage can fairly compete not only with the dry, hot, dusty air of Continental towns, but with the choicest resorts of the country. The proprietors of the English watering-places have much to learn from Continental rivals; and so, perhaps, have the English visitors, who, by open and easier manners in their intercourse with each other, would add greatly to their own cheerfulness, enjoyment, and health.

“The salubrity of the English watering-places admits, too, of improvement; but all the sanitary arrangements contrast favourably with the inconveniences and insalubrities abroad, which are likely to be tested by the coming epidemic.

“With regard to the copious drinking of the various waters which still survives under the auspices of German doctors, it has apparently, like blood-letting, lost favour in England; but those who still have faith in the miraculous influences of solutions of the various salts, gases, and sulphur need lack no indulgence in English inland watering-places.

“In Table X. will be found figures showing the recent

death-rates from all causes, and also from the seven principal zymotic diseases, in each of the largest sea-side and inland watering-places on the coast of England and Wales during the quarter ending the 30th of June last. The forty-seven places with which this table deals contained, on the 3rd of April last, a population of rather more than a million of persons, among which the death-rate during last quarter was only 18 per 1,000. The rate in the several places ranged from 12 in Folkestone, and 13 in Weston-super-Mare, to 25 in Aberystwith, and 28 in Weymouth. Worthing, Sidmouth, Llandudno, Malvern, Lowestoft, and Margate were most conspicuous for their freedom from deaths of a zymotic character, while the highest death-rate from these diseases was shown in Tunbridge Wells, New Brighton, and Weymouth. In Tunbridge Wells 14 deaths from scarlet fever and five from small-pox were reported; in New Brighton (Lancashire) five from scarlet fever, four from small-pox, and three from measles; in Weymouth small-pox was severely epidemic, and caused 39 deaths.”

### Exercise in High Temperatures.

SOME curious facts are related in the report of the Coal Committee. In some cases men have carried on their work in a temperature of 180 deg. Fahr., but this heat was much of it due to radiation. This may be a source of considerable error, for, in one experiment, a thermometer suspended in a stoke-hole, and exposed to the radiation from the boilers, indicated a temperature of 105 deg.; while another thermometer in the same position but carefully screened from the radiant heat, stood at only 78 deg. Men who work in stoke-holes and glass-houses have ready access to the external air, and avail themselves of numerous intervals in their labour to cool themselves. One Medical witness, who had spent a great part of his life in tropical climates, stated that he had experienced a temperature of 125 deg. Fahr. in the shade, and that this great heat was rendered endurable by the dryness of the atmosphere; on the other hand, he had felt a damp atmosphere almost intolerable at the comparatively low temperature of 86 deg. Hearing of mining work being executed in a Cornish mine where the air was heated by a hot spring to a temperature alleged to amount to 117 deg., and was also by the same cause saturated with moisture, the Committee requested Dr. Sanderson to visit this mine, and he found the highest temperature to exist at the extremity of an excavation forming a short *cul de sac*, where a stream of water entered at a temperature of 114½ deg. At a distance of a yard from the end of this *cul de sac* the thermometer indicated a temperature of 103 deg.; but at a distance of only ten feet there was access to air, where the thermometer stood at 81 deg. He was told that the temperature of the air occasionally reached 123 deg. The miners remained in their workings six hours out of the twenty-four. Four men were employed at a time, of whom two were always at rest in the cool air, and the other two were not always at work. The total duration of each man's work was less than three hours in the twenty-four. No miner remained more than fifteen minutes in the heat at one time. The condition of each miner on retreating into cool air is described as one of complete exhaustion; but by allowing cool water to pour over his body the distress and exhaustion quickly passed off. Dr. Sanderson came to the conclusion that the occupation in question was not necessarily inconsistent with the enjoyment of vigorous health; but he found that there were many men who, after trying

the work, were compelled to desist on account of the distress and exhaustion which was produced. It is Dr. Sanderson's opinion that labour is not practicable in moist air of a temperature equal to that of the blood—namely, 98 deg., excepting for very short intervals; and this conclusion is in harmony with the other Medical evidence. The question of maximum temperature under which work could be carried on in a coal mine hinges in a great measure on the hygrometric condition of the air. The depth at which the temperature of the air would under present conditions become equal to the heat of the blood would be about 3,420 feet; but the Committee looking to possible expedients, which the future may elicit for reducing the temperature, considered it might fairly be assumed that a depth of at least 4,000 feet might be reached.

### Pauperism.

ACCORDING to the Registrar-General's report the average number of paupers relieved on the last day of each week in each of the last three winter quarters was as follows:—

| Quarter ending      | In-door. | Out-door. |
|---------------------|----------|-----------|
| 30th June, 1869 ... | 145,094  | 816,260   |
| " " 1870 ...        | 144,226  | 825,337   |
| " " 1871 ...        | 140,338  | 805,519   |

The extreme depression of temperature which prevailed at the end of the past year and during January of the present year, after yielding to spring-like warmth, again became low, and the weather was relatively colder in June than in the former months of the year.

During the three months the average temperature was 1.6° below that of the past thirty years.

### Rare Medical Eloquence.

In a paper read before the Tennessee State Medical Society, by Dr. C. C. Abernathy, the *New York Medical Report* finds the following grandiloquent tribute to blood-letting:—

"I regard the almost general abandonment of the lancet as a great public calamity. I believe that untold numbers of precious lives have been lost for want of timely and judicious blood-letting, and myriads more are doomed to fill premature graves, unless we retrace our steps, and start anew in the right direction. In my humble opinion, it were well that we imitate the example of Armstrong, Eberle, Chapman, Stokes, Phisic, Wood, and other great lights of the profession, in doing homage to this time-honoured and reliable remedy—a remedy which, crowned with laurels of triumph on thousands of hotly-contested fields, is still destined (I fondly trust) to march proudly, confidently forward in her glorious mission of restoration, bearing in her regal train countless votaries—mothers, who burn incense upon her altars in commemoration of precious little ones rescued by her benign influence; husbands, who sing anthems of praise in her honour, while they fondly embrace the sharers of their joys and sorrows, and signalise them as trophies, which she has promptly restored to health and beauty; while matron and maiden, old and young, all vie in doing her such honour as none save the meritorious and truthful deserve. Beholding disease, in her protean forms, attacking, with relentless fury the citadel of life, she speaks, and, like Joshua of old, is obeyed—she cries, 'Peace, be still,' and the troubled waters are quieted."

### Public Health.

THE Registrar-General's last return shows a considerable increase in the number of deaths, there having been

1,568, and only 1,382 in the previous week. The increase is not due to any particular disease or epidemic. Thus there are, as compared with the previous week, 9 more deaths from small-pox, 10 from measles, 6 from scarlet fever, 16 from whooping cough, 6 from typhoid fever, and 74 (chiefly infantile) from diarrhoea. The deaths from English cholera are fewer than in the previous week. The annual rates of mortality in the following places, per 1,000 of the population, were:—Wolverhampton, 9; Dublin, 16; Hull, 17; Portsmouth, 19; Bristol and Birmingham, 20; Norwich, Edinburgh, and Bradford, 21; London, 25; Nottingham, 26; Leicester, 29; Liverpool, 30; Salford, 31; Glasgow, 32; Sheffield, 33; Manchester, 34; Newcastle-on-Tyne, 39; and Sunderland, 51.

### Leprosy.

A LETTER from Valencia in the *Esperanza* of Madrid, says:—"Leprosy has just made its reappearance at Rafelcofer. The Governor of the Province has given orders to the sub-delegate of the Board of Health in the district of Gandia, in which that village is situated, to make a report on the origin of this frightful disease."

### The Cholera in Russia.

THE *Standard's* correspondent writing from St. Petersburg, August 4, says:—

"It is nearly a year since the cholera appeared here, and, after giving us a long respite during the winter, it has again broken out with renewed intensity. The measures adopted by the sanitary commission of St. Petersburg have rendered the epidemic comparatively harmless in the capital, but the filthy state of some of the provincial towns has favoured its progress in the country, and many of the reports from the interior show a heavy mortality in proportion to the population. The following is the latest St. Petersburg bulletin:—Cases remaining, 476, new cases, 33, deaths, 18. From the first appearance of the cholera on the 29th of August, 1870, there have been in St. Petersburg, 6,817 cases, and 2,797 deaths. In Moscow and its environs the epidemic is of a very malignant character, and in some remote villages, where medical assistance is difficult to obtain, it has committed fearful ravages."

### Adulteration.

A CIRCULAR on the above subject has been issued by the Anti-Adulteration Association, Limited. The Association's objects are to enforce and amend the laws on the subject, the enforcement to be carried out by appointing analysts throughout the country, and by the prosecution of wholesale distributors of adulterated articles. The offices are at 6 John street, Adelphi, where prospectuses may be procured.

### Solvent Properties of Anhydrous Liquid Ammonia.

PROFESSOR SEELY, writing to the *American Journal of Applied Chemistry*, claims to have made the discovery that anhydrous liquid ammonia has a solvent power upon certain metals, and he has actually succeeded in obtaining a solution of sodium in this liquid. The solution presents all the physical characteristics of a true solution. On evaporation the sodium is gradually restored to the metallic state in the same continuous manner in which the solution has been effected. The colour of the solution is a very intense blue.

### Poison "by Misadventure."

ONE of those insignificant little errors to avoid which the Members of the Pharmaceutical Society think it a great hardship to be asked to arrange their poison cupboards has just occurred at Salcombe, near Sidmouth. A poor gentleman named Wall got a drachm of solution of morphia in his mixture instead of a scruple.

The druggists shrug their shoulders and say, "*Humanum est errare*—what a bother you make about an occasional little mistake."

We say it is just because chemists are mortal that they should be compelled to protect the public against mortal aptitude to error whether they like it or not.

### A New Reason for Economy of Medicine.

THE Islington Guardians, through their chairman, disapprove of tinctures being ordered by their doctors and supplied to their dispensaries, on the ground that they lead to habits of intemperance.

### Palmgren.

A PREPARATION just being introduced in the American market, and recommended to cure consumption in all its stages. Here it is:—

|                         |     |     |                  |
|-------------------------|-----|-----|------------------|
| Palmstarch              | ... | ... | 1 part           |
| Sugar                   | ... | ... | 9 "              |
| Chestnutmeal            | ... | ... | 1 "              |
| Burnt and Ground Coffee | ... | ... | $\frac{3}{4}$ "  |
| Powdered Cacao          | ... | ... | $1\frac{1}{4}$ " |
| Ricemeal (flour)        | ... | ... | 1 "              |
| Arrowroot               | ... | ... | 1 "              |

—*American Medical Gazette.*

M. THIERS has appointed Mr. O'Scanlan, the director of the Irish Ambulance during the war, to be a Chevalier of the Legion of Honour. The principal persons connected with that ambulance will also receive decorations.

THE Sanitary Committee of the Vestry of St. Mary, Islington, will meet on Sept. 18 to consider the applications from legally-qualified Medical Practitioners desirous of filling the office of Medical Officer of Health and Analyst for the parish, at a salary of £250 per annum.

WE learn from the list published in the *British Medical Journal* that four members of the Profession from Ireland attended the recent meeting at Plymouth. We also observe that when at the Annual Dinner the healths of the Irish and Scotch members was proposed—no one but a Mr. Leicester responded.

THE Paris Academy of Science has discovered that the chloride contained in salt water is the essential element for sea fish and the poisonous agent towards fresh-water fish. M. de Bert removed these chlorides from sea-water and found that river fish lived in it, and salt-water animals died. Does this rule apply to all fish? We have ourselves kept the common sticklebacks of our ponds for three days in the same sea aquarium as actinia, and when then expelled for their ferocity, they were as lively as ever.

AN apology appears in the columns of a medical temporary from James Dore Blake, of Taunton, practising as a Doctor of Homœopathic Medicine by virtue of a Degree in Medicine granted to me by the Pennsylvanian College of Homœopathic Medicine in Philadelphia, for having, contrary to and in breach of the Lunacy Acts, unlawfully signed a certificate for the admission of a lunatic into a house licensed for the reception of lunatics, I not being a Physician, Surgeon, or Apothecary registered under the Medical Act.

AN election to the Office of Fourth Physician in the Queen's Hospital, Birmingham will take place on Friday, September 8th, 1871. Candidates for this office must be graduates in medicine of an University. The election will be made by a Special Committee of Governors, 100 in number; and the appointment of this Special Committee will take place on Friday, August 25.

The duties of the Fourth Physician are as follows:—  
"He shall have four beds for the reception of in-patients, and two days in the week to see out-patients."

"He shall set apart one hour weekly during the Session for instruction in percussion and auscultation, the use of the thermometer, laryngoscope, ophthalmoscope, and microscope, and the examination of the urine.

At the Summer Assizes at Croydon, on August 12, an action for negligence was brought against a medical practitioner who has been established upwards of twenty years in Southwark. It was said that a working woman called at his shop and asked an assistant for "*Rochelle salts*," but he said she asked for some other salts, and he gave her carbonate of potass (charging her one penny), of which she took a spoonful in water, and it caused her violent vomiting and great pain. Soon afterwards an attorney's clerk called upon the doctor for compensation, and he, in order to avoid the vexation of an action, offered to pay £40 or £50, but in vain. After a long trial the learned Baron summed up the case. If, he said, the assistant had understood the woman as asking for Rochelle salts, and had given her the carbonate for it, or if he had not taken care to ascertain what it was she wanted, the defendant would be liable, but if he gave her what she asked for, then as she did not ask for directions about its use (though it would have been better to have given them) the defendant was not liable. Even, however, though the jury found for the plaintiff there would remain the question of damages, as to which the learned judge observed there were many circumstances which required consideration. The case must be looked at as a whole, and there was strong evidence of undoubted witnesses that the woman had sustained no real injury at all. Moreover, there was great reason to suspect that it was the attorney's clerk rather than the woman who was interested in the action. The jury, after a brief consultation, gave a verdict for the plaintiff for one farthing.

Death from Wearing False Teeth.—On Wednesday an elderly man applied for a bed at a lodging-house in Charles-street, Drury lane. In the morning he was found in the back yard insensible and in a dying state. He was conveyed to St. Giles's Workhouse and examined by Dr. Carr, but life was extinct. On opening his mouth a set of false teeth was discovered out of its proper position, which it is supposed interfered with his breathing and caused his death. No documents have been found on the deceased to lead to his identity.

## Correspondence.

### DR. MADDEN'S EDITION OF THE DUBLIN PRACTICE OF MIDWIFERY—THE DUTIES OF VAGINAL BAPTISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I kindly request you to give insertion to a few sentences in reference to your "moral critique," or review on the book called the "Dublin Midwifery Practice." That book was never a voluminous work on the art or practice of midwifery, but a mere handbook for a student. While a student, I long thought the short forceps, as then used, were often found *too thick* or clumsy in the blades. Since I entered into midwifery practice, I have attended many cases where the smallest point of the finger would be *painfully hurt* in being brought into contact with the head and the maternal structures in cases, where, from accidental causes, the labour had been prolonged, *i.e.*, converted into difficult labour, by the unnatural extension of the time without delivery by the natural way. In some of those the child was found dead, but had been pronounced by the mother to have been alive within a few hours; in one case, within half an hour, and in this case the woman suddenly took convulsions, which, being relieved by the exhibition of "chloroform vapour," on examination a few minutes after, I found the fetal heart's tick, no longer audible, but only the "bruit placental." As I always, when I suspect, for clear reasons there is danger to the infant's life, give private baptism as a conditional rite if the child be alive; since if it be dead, that condition is *ipso facto* prohibited, in the former case the weightier responsibility rests on the medical attendant, for in the latter it matters little, *celoris paribus* how the woman is delivered. The safest and easiest manner the best. But in this state also the medical practitioner may have neglected the plain duty of lay baptism, and if so he has no remedy left him. It is well to baptize the foot or hand, water can be applied to the head with tow, or sponge, or what is the best the nozzle of a syringe can, with the index and middle finger of the left hand, be applied to the head (in utero, or in transitu), while the operator holds the instrument in the right hand. In this way a good stream of water can be directly applied to the infant's head. Just at the time of the occurrence of the cases alluded to, I read with great delight the lectures of Dr. Madden on the subject, these lectures having been published in the MEDICAL PRESS AND CIRCULAR in 1868 or 1869, as delivered by Dr. Madden, in the Rotunda Hospital. I believed the short forceps introduced by Dr. Madden are of great "bona fide" value, for these reasons, the want observed in certain cases as I refer to, of an instrument with less clumsy blades than either Drs. Churchill's or Beatty's, is well supplied, the blades are somewhat larger in consequence of the fenestra, so that the force applied is more extended, and therefore less subject to cause injury than the old forceps. I have often used the forceps both of Drs. Churchill and Beatty, often seen them used too much and too long from the effects that followed, yet far from disparaging their strength or utility as mechanical agents, I should use them if I had no others, but while I am provided with those of more modern skill, and better design for these very troublesome cases of midwifery, where I say the point of the finger is painfully pinched—and where the time has gone too far before delivery, where there exists no real hope of overlapping (any longer) of the fetal sutures, and where the child is alive, "where the patient is growing" weaker hour by hour, I must respectfully bear testimony to the increased facilities afforded in Dr. More Madden's forceps (as manufactured by Mr. Whyte, Dublin). It matters to me very little by what name those forceps are called, so long as they afford any help against "craniotomy" which can never be referable to any case unless where distinct signs are present, that the infant is dead—one surgeon of eminence told me, "I should not like to have a number of those little things after me for eternity, I avoid all such interference with Divine Law." But not to speculate beyond the grave, it is quite certain we should have neither Doctors Churchill, nor Beatty, or Madden, had the cephalotribe been "dug" into their heads, which inductively proves to me, what little things come to. I once was called on to attend a Jew's child, I found it labouring under infantile hernia, that individual wished me to send it to eternity with a "dose of some drug." I looked upon the

person in a sense opposed to the "Decalogue," and said, if he were to ask me twice, I should apply to have him brought before the criminal law courts. This letter has already become prolix. I shall only add as a reader, my opinion of your review on Dr. Madden's edition of the Dublin practice is entirely without merit and less intelligence. I give you my reasons for saying so. 1st. Because you approved of the book as formerly edited. 2nd. That such a book is fit in every respect to impart any practical knowledge to a student passing his examination on the subject of the "Forceps," Now the book as it stands is just the same as before, but it has been improved, therefore you seem unjust to Dr. Madden and the entire profession in your marvellous and silly review.

I have the honour to remain faithfully,

JOHN O'REILLY, L.R.C.S., L.K.Q.C.P.,  
Medical Officer, Nobber, Co. Meath.

August 5th, 1871.

### ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

The Treasurer of the above Society begs to acknowledge the following contributions received from Dr. Erskine, Hon. Sec. and Treasurer to the Newry Branch:—

|                                 |        |
|---------------------------------|--------|
| Dr. Vesey, Rostrevor . . . . .  | £1 1 0 |
| Dr. Gray, Moorvale . . . . .    | 1 0 0  |
| Dr. McBride, Forkhill . . . . . | 0 10 0 |
| Dr. McBride, Newry . . . . .    | 0 10 0 |
| Total . . . . .                 | £3 1 0 |

## Parliamentary Intelligence.

### FOREIGN DECORATIONS.

IN the House of Commons on Thursday last, Mr. EYKYN asked the noble Lord the Under Secretary of State for Foreign Affairs to state the circumstances under which Dr. Gordon was refused permission to wear the orders which were given to him by the authorities of France for the services which he rendered during the siege of Paris, and why a distinguished officer of the Coldstream Guards had been permitted to wear his.

Lord ENFIELD said that the services of Dr. Gordon in Paris in the early part of the last winter were permitted under the immediate sanction and knowledge of the Secretary of State for War, and therefore, according to the rules and regulations, he would be allowed to wear them, but no application for him to do so had been made by the French authorities to Her Majesty's government. The house would allow him to correct a misapprehension into which he fell on Friday last with regard to the services of Dr. Gordon and Surgeon-Major Wyatt, and the benevolent and humane exertions of the ladies and gentleman who acted under the Geneva convention, that they rendered those services on their own account, and that they were not required to report to Her Majesty's government. He had since found he made a mistake, and that Surgeon-Major Wyatt and Dr. Gordon did apply to the Secretary of State for War, and that they acted under his immediate knowledge and sanction, and that Her Majesty's government entertained a high sense of the valuable services performed by them in Paris.

### REPORTED CASE OF CHOLERA IN LONDON.

MR. DENMAN asked the Vice-President of the Council in the House of Commons on Tuesday, whether his attention had been called to a letter signed by Dr. Edmunds, and published in a newspaper that morning, stating that he had been called in to attend a typical case of Asiatic cholera.

MR. W. E. FORSTER, in reply, said:—I am informed by the medical officers of the Privy Council, that immediately on seeing this letter Dr. Buchanan was sent from the office to examine the case, and make a report.

I am very glad to say, from that report, that there is reason to believe it was not a case of Asiatic cholera, although there were symptoms at first that might have excited suspicion that such was the case. The patient seems to be a respectable artisan, employed in some works, and also a school teacher, and was taken ill last night on returning from a school treat. Certainly when Dr. Edmunds was called in this morning the patient had a bad attack of cholera, and was in a state that might naturally have excited suspicion that the attack was Asiatic in its character, though there is now reason to suppose that it was not so; at any rate, the patient is now much better. I rather regret that Dr. Edmunds did not wait a few hours before writing to *The Times*, because if he had so waited I do not think he would have thought it necessary to write a letter causing needless alarm. But whether he was right or not in doing this, there is one matter to which I should wish to call the attention of medical gentlemen throughout the metropolis and the kingdom generally. Dr. Edmunds appears to have contented himself with sending this letter to *The Times* instead of communicating with the sanitary authorities of Marylebone, which, undoubtedly, it was his clear duty to do. If medical gentlemen entertain any suspicion of such cases in their own neighbourhood, they should immediately send to the sanitary authorities, whose duty is to take all proper measures for disinfection.

#### ARMY MEDICAL REPORTS.

ON Friday evening Lord ELCHO asked the Secretary for War if he would lay on the table a copy of the late war on behalf of Her Majesty, and who, he understood, had made very important recommendations with regard to the treatment of the sick and the best sanitary arrangements to be adopted in the field.

MR. CARDWELL declined to comply with the request of the noble lord, reminding him that it was undesirable to produce the reports of officers who had been sent to report on foreign armies.

## Medical News.

**Gig Accident.**—A sad accident has occurred at Godney Hall, near Wisbech. Dr. Crowden, a medical man, accompanied by Mrs. Crowden, was driving along the road at the top of Southean Bank, when the horse took fright at the squeaking of a pig, and dashing down the embankment, overturned the gig and threw out the occupants. Dr. Crowden had his collar-bone broken, and his wife, besides being severely bruised and shaken, had both ankles broken. One leg has been amputated five inches above the ankle, and hopes are now entertained of her recovery.

**Donations, Bequests, etc.**—"C. D. W." has given another £1,000 to the Hospital for Sick Children, Great Ormond street. Miss Elizabeth Kingston, of Harpenden, Herts, bequeathed £500 Three per cent. Consols each to the Asylum for Idiots, Redhill; the British Home for Incurables, Clapham rise; and the Infirmary, Hemel Hempstead. Mr. Humphrey Nicholls has given £100 to the Clinical Hospital, Park place, Cheetnam hill; and the Ardwick and Ancoats Dispensary, Manchester. Mr. Benjamin Chandler bequeathed £100 to the General Hospital, Birmingham. Mr. John Thomas Murphy bequeathed £200 to the City of Dublin Hospital. Lady Staples has given £50 towards the funds of the Idiot Institution at Luan.

**Health of the Queen.**—The Queen accomplished the journey to Balmoral without any unusual suffering, but the next day was so unwell as to be unable to leave her own apartments, and join the family circle. Her Majesty's visit to the Duke and Duchess of Argyll, has been indefinitely postponed.

#### NOTICES TO CORRESPONDENTS.

TO OUR SUBSCRIBERS.—Gentlemen who have not paid their subscription for last year are respectfully reminded of the omission. The Publishers would also be much pleased to receive arrears of subscriptions due for several years previously, which, in too many instances, remain unpaid, notwithstanding frequent applications for settlement.

NOTICE.—Subscribers are respectfully reminded that payment by P.O.O., or crossed cheque, is the most convenient and safest mode of remittance. Stamps are unfortunately too easily disposable by dishonest persons.

All valid receipts are given upon printed forms. Subscribers and advertisers are particularly cautioned against making any payments without the production of such a receipt. Cheques or P.O.O. should be made payable in England, to A. A. Tindall; in Ireland, to A. H. Jacob, M.D.; in Scotland, to MacLachlan and Stewart.

**TONTINE.**—We believe the Alexandra Palace has been erected with all modern improvements in public buildings. The views from the terraces and the interior of the building are said to resemble those of the Malvern or Surrey Hills. The railway facilities will give to the inhabitants of the Metropolis access to one of the finest and best recreation grounds in Europe. Investors are covered by insurance of 20s. for every 21s., so that no risk is incurred, and the profits every year are cumulative in advantages.

**DR. M.**—The Report of the Contagious Diseases Commission has already been published. It is expected the evidence will shortly appear.

**SANITAS** hits the nail on the head in reference to dustbins and disease. In a note to a contemporary "Sanitas" says—The nuisance could be at once done away with if householders would prohibit the practice by lazy servants of making the dustbin a receptacle for all kinds of decaying matter and other rubbish. If nothing but cinder-ash were permitted to be thrown in the dust-bin there would be no "nuisance" at all! Cabbage-stalks, potato-peelings, fish-bones, and all such useless articles, could be burnt. These regulations should be enforced by the authorities, who should institute a house-to-house inspection and levy a fine in all cases of neglect; if this plan were carried out we should hear no more of the dust-bin as a fever-nest and a propagator of cholera, which it now is.

#### PASS LIST SUPERSEDED.

A local paper contains the following:—On the 2nd inst., Dr. Fothergill (member of the Royal College of Surgeons of England, and Licentiate of Midwifery of Edinburgh), Hesketh-new-Market, after undergoing the necessary examinations, received the license of the Royal College of Physicians of Edinburgh to practise as a physician.

The following communications are in type, and will appear, if possible, in our next:—

W. E. Teevan, B.A., F.R.C.S., "Case of Retention of Urine from Impassable Stricture, treated by Filiform Bougies."

G. Smith Chartres, M.A., M.D., "Syphilitic Iritis attacking both Eyes in succession, treated principally by Oil of Turpentine and Blisters."

Dr. Francis M. Luther, "Case of Progressive Locomotor Ataxy."

#### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A Manual of the Laws Affecting Medical Men. By R. G. Glim, Barrister-at-Law. London: J. and A. Churchill.

Our Eyes, and How to Take Care of Them. By H. W. Williams, M.D. London: Tegg and Co.

West Riding Lunatic Asylum Medical Reports. Vol. I. London: J. and A. Churchill.

Professional Grievances. By W. Ogle, M.A., M.D., Derby.

Reports of the Metropolitan Board of Works. Prospectuses of St. Bartholomew's, and the London Hospital Medical Schools.

#### APPOINTMENTS.

EVANS, G. H., M.D., Resident Assistant-Physician at St. Thomas's Hospital.

GARRINGTON, A. M., M.D., M.R.C.S.E., Surgeon to Portsmouth Gaol.

GIBSON, C. H., L.R.C.P.Ed., L.R.C.S.Ed., M.R.C.S.E., Assistant Medical Officer for the Idiot Branch of the Warwick County Lunatic Asylum.

GRAY, A. R., M.D., M.R.C.S.E., Assistant Medical Officer at the Broadmoor Criminal Lunatic Asylum.

LAW, W. T., M.R.C.S.E., Resident Physician to the Royal Infirmary, Edinburgh.

LAWRIE, E., M.B., M.R.C.S.E., Resident Medical Officer at the General Hospital and Dispensary for Sick Children, Manchester, vice J. Moffat, M.D., L.R.C.S.Ed., resigned.

LOWSE, H. T., M.R.C.S.E., Lecturer on Physiology at the Middlesex Hospital Medical College.

MOORE, Dr. E., Honorary Medical Officer to the Preston and County of Lancaster Royal Infirmary, vice Dr. Malling, deceased.

NEWTON, R. C., M.R.C.S.E., Visiting Surgeon for the Out-patient Department of the Newcastle-on-Tyne Lying-in Hospital.

NORTH, J. C., M.B., C.M., House-Surgeon to the Brecknock Infirmary, vice J. T. Jones, M.B., M.R.C.S.E., promoted to Physician.

PARRIDGE, J. H., M.R.C.S.E., Surgeon to the Essex and Colchester Hospital.

ROUSE, J., F.R.C.S.E., Hon. Consulting Surgeon to the Royal Asylum of St. Anne's Society.

SMITH, W. R., L.R.C.P.Ed., L.R.C.S.Ed., House-Surgeon to the Huddersfield Infirmary, vice Booth, resigned.

WALKER, S., M.R.C.S.E., Surgeon to the North Riding Infirmary, Middlesbrough-on-Tees, vice J. Ellerton, M.D., resigned.

WHITHEAD, A., M.R.C.S.E., Resident Medical Officer at the Birmingham and Midland Free Hospital for Sick Children, vice A. S. Underhill, M.B., C.M., resigned.

WILSON, H. O., M.R.C.S.E., Hon. Medical Officer to the Wirral Hospital and Dispensary for Sick Children, Birkenhead, vice Dr. W. Forbes, resigned.  
 WRIGHT, Mr. F. W., Assistant Resident Medical Officer at the General Infirmary, Leeds.

## Deaths.

A'BECKETT.—On the 23rd of May, at Sydney, New South Wales, Arthur M. a'Beckett, aged 58.  
 BERNARD.—On the 10th inst., Ralph M. Bernard, F.R.C.S.E., of Clifton, Bristol.  
 KENDALL.—On the 15th inst., at King's Lynn, Thos. M. Kendall, F.R.C.S., L.S.A., aged 51. No Cards. Friends will please accept this intimation.  
 NEWBOLD.—On the 7th inst., Ambrose Newbold, L.K.Q.C.P.I., M.R.C.S.E., of Carnew, Co. Wicklow, aged 44.  
 SYNNOT.—On the 9th inst., at Lisnasca, Co. Down, Robert Synnot, M.D., late of Royal-avenue, King's-road, Chelsea, aged 52.  
 THOMAS.—On the 1st of June, Dr. David John Thomas, of Melbourne, Victoria.

## Advertisements.

### ST. THOMAS'S HOSPITAL.

THE MEDICAL SESSION for 1871 and 1872, will commence at the NEW HOSPITAL on the Albert Embankment, Westminster Bridge, S.E., on MONDAY, the 2nd OCTOBER, 1871, on which occasion an INAUGURAL ADDRESS will be delivered by MR. LE GROS CLARK, at Two o'clock, after which the DISTRIBUTION OF PRIZES will be made by SIR FRANCIS HICKS, Treasurer.  
 Gentlemen entering have the option of paying £10 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105, at once of becoming perpetual Students.

#### PRIZES & APPOINTMENTS FOR THE SESSION.

First Year's Students. WINTER PRIZES—£20, £15, and £10. SCHOLAR PRIZES—£15, £10, and £5.

THE Wm. TITE SCHOLARSHIP, founded by Sir Wm. Tite, C.B., M.P., F.R.S., the proceeds of £1,000 Consols, tenable for three years, is awarded every third year.

Second Year's Students. WINTER PRIZES—£20, £15, and £10. SCHOLAR PRIZES—£15, £10, £5. THE DRESSERSHIPS, and the CLINICAL and OBSTETRIC CLERKSHIPS.

Third Year's Students. WINTER PRIZES—£20, £15, and £10. MR. GEORGE VAUGHAN'S CHESEBOLD MEDAL. THE TREASURER'S GOLD MEDAL. THE GRAINGER TESTIMONIAL PRIZE. THE TWO HOUSE PHYSICIANSHIPS. THE TWO HOUSE SURGEONSHIPS. THE RESIDENT ACCOUCHEURSHIPS. TWO MEDICAL REGISTRARSHIPS, at a Salary of £40 each, or one at £50, are awarded to 3rd and 4th years' Students, according to merit.

#### MEDICAL OFFICERS.

*Honorary Consulting Physicians.*—Dr. Barker and Dr. J. Risden Bennett.  
 Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Marchison, Dr. Barnes, Mr. Le Gros Clark, Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. Liebreich, Dr. Stone, Dr. Ord, Dr. John Harley, Dr. Payne, Dr. Gervis, Mr. MacCormac, Mr. Francis Mason, Mr. Hy. Arnott.

*Medicine.*—Dr. Peacock and Dr. Marchison. *Surgery.*—Mr. Le Gros Clark and Mr. Sydney Jones. *General Pathology.*—Dr. Bristowe. *Physiology and Practical Physiology.*—Dr. Ord and Dr. John Harley. *Descriptive Anatomy.*—Mr. Francis Mason and Mr. W. W. Waestafel. *Anatomy in the Dissecting Room.*—Anatomical Lectures—Mr. Ruiney and Mr. Wm. Anderson. *Chemistry and Practical Chemistry.*—Dr. A. J. Bernays. *Midwifery.*—Dr. Barnes. *Practical and Manipulative Surgery.*—Mr. Croft and Mr. MacCormac. *Physics and Natural Philosophy.*—Dr. Stone. *Materia Medica.*—Dr. Clapton. *Forensic Medicine and Hygiene.*—Dr. Stone and Dr. Gervis. *Comparative Anatomy.*—Mr. C. Stewart. *Ophthalmic Surgery.*—Mr. Liebreich. *Botany.*—Dr. Wale Hickes. *Dental Surgery.*—Mr. J. W. Elliott. *Demonstrations Morbid Anatomy.*—Dr. Payne. *Mental Diseases.*—Dr. Wm. Rhys Williams. *Geographical Distribution of Diseases in England and Wales.*—Mr. A. Haviland.

R. G. WHITFIELD, Medical Secretary.

T. B. PEACOCK, M.D., DEAN.

For entrance or Prospectuses, and for information relating to Prizes and all other matters, apply to Mr. WHITFIELD, Medical Secretary, The Manor House, St. Thomas's Hospital, Newington, Surrey, S.E.

### THE MIDLAND RETREAT

(Near Maryborough, on the Great Southern and Western Railway.)

FOR THE RECEPTION and TREATMENT of the INSANE, and of persons suffering from a disturbed state of the Nervous System, under the direction of DR. JACOB, Physician to the Maryborough District Lunatic Asylum (250 patients), Surgeon to the Queen's Co. Infirmary, &c.

THE ESTABLISHMENT consists of separate and commodious residences for the reception of Ladies and Gentlemen. Each situated on extensive grounds, with large, well-enclosed gardens. They are handsome, well-furnished country residences, where the patients enjoy the comforts and indulgences of a private house. Restraint is not, under any circumstances practised, and the closest attention is paid to the medical treatment and general health of the patients.

### ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION will commence on MONDAY, 2nd OCTOBER, with an Introductory Address by Dr. John Clarke, at 2 p.m., in the Hospital.

Consulting-Physicians—Dr. Wilson, Dr. Bence Jones, Dr. Pitman Physicians—Dr. Fuller, Dr. Barclay, Dr. John Ogle, Dr. Wadham Assistant-Physicians—Dr. Dickinson, Dr. William Ogle. Physician-Accoucheur—Dr. John Clarke. Consulting-Surgeons—Mr. Cesar Hawkins, Mr. Cutler, Mr. Tatum. Surgeons—Mr. Hewe\*, Mr. Pollock, Mr. Henry Lec, Mr. Holmes. Assistant-Surgeons—Mr. Rouse, Mr. Pick. Ophth. Surgeon—Mr. Brudenell Carter. Orthopædic Surgeon—Mr. Brodhurst.

A Maternity Department and Departments for Ophthalmic and Dental Surgery are arranged in connexion with the Hospital School.

#### LECTURERS.

Descriptive and Surgical Anatomy—Mr. Rouse.  
 Physiology and General Anatomy—Dr. Wm. Ogle.  
 Physiological Histology—Dr. Cavafy.  
 Chemistry—Dr. Noad, F.R.S.  
 Physiological Chemistry—  
 Medicine—Dr. Barelay.  
 Psychological Medicine—Dr. Blandford.  
 Surgery—Mr. Holmes.  
 Ophthalmic Surgery—Mr. Brudenell Carter.  
 Orthopædic Surgery—Mr. Brodhurst.  
 Operative Surgery—Mr. Pick.  
 Pathology and Morbid Anatomy—Dr. Dickinson.  
 Midwifery—Dr. John Clarke.  
 Materia Medica—Dr. Dickinson.  
 Forensic Medicine—Dr. Wadham.  
 Dental Surgery—Mr. Vasey.  
 Botany—Mr. Child, F.L.S.  
 Comparative Anatomy—Dr. Cavafy.

Clinical Lectures by the Physicians and Surgeons every week. A Medical Tutor is appointed to superintend the studies of the Pupils, and hold periodical examinations.

On payment of one hundred guineas at entrance, a Pupil becomes perpetual to the Hospital Practice and all the Lectures.

Compounders pay forty guineas on admission, forty guineas for the second year, and ten guineas for each subsequent year, until their payments shall have reached one hundred and ten guineas, when they become Perpetual Pupils.

Gentlemen may enter separately to Medical or Surgical Practice, or to any single course of Lectures.

Dental Pupils are admitted on payment of £45.

Special Demonstrations of Skin Diseases and Lectures on Public Health will form part of the course of Lectures on the Practice of Medicine; and Students will be required also to attend the separate courses of Lectures on Pathology and on Psychological Medicine.

In connexion with the Lectures on Surgery, Demonstrations will be given on the Use of the Laryngoscope. A separate course of Lectures on Diseases of the Eye, with Demonstrations of the use of the Ophthalmoscope, will be given, as well as Lectures on Orthopædic Surgery, with Illustrations of Deformities and their Treatment. Attendance on each of these courses will be required of Surgical Pupils.

In the Maternity Department, special Clinical Instruction will be given on Diseases peculiar to Women, and Practical Instruction in Vaccination to those who require certificates of proficiency.

*The Appointments of House-Physician and House-Surgeon, which are held for twelve months, are filled up half-yearly from among the Senior Students, according to merit. These Officers now receive their Board and Lodging free, and no payment is made for the Appointment.*

*Clinical Clerks and Dressers are also appointed without payment, and provision is made that each Student should have the opportunity of holding these offices during his attendance.*

These offices of Obstetric Assistance, Curator of the Museum, Medical and Surgical Registrars, and Demonstrator of Anatomy, with salaries of from £50 to £100 attached to each, are held out for competition annually. The William Brown Exhibition of £40 per annum, tenable for three years, is bestowed after a competitive examination. Clinical Prizes are offered annually by Sir Benjamin Brodie, Dr. Acland, and by the Treasurer of the Hospital. Sir Charles Clarke's "Good Conduct" Prize, the Thompson Medal, and the Johnson Memorial Prize are also to be competed for each year. A general examination of all the Students is held at the end of the Summer Session, and Prizes and Certificates of General Proficiency are given to the most deserving.

Further information may be obtained from Dr. Barclay, the Treasurer, or Dr. Wadham, the Dean of the Medical School, and from any of the Lecturers and Medical Officers of the Hospital.

#### WESTMORELAND LOCK HOSPITAL.

The BOARD of GOVERNORS of this Hospital, will, at their Meeting on SATURDAY, the 26th inst., at the hour of One o'clock P.M., proceed to elect a Gentleman, duly qualified to act as

RESIDENT APOTHECARY and ACCOUCHEUR to the Institution. Salary Seventy-five pounds per annum, with Furnished Apartments, fuel and light, but without any other emoluments or fees whatever.

Applications, enclosing Diplomas and Testimonials, to be addressed to "The Chairman of the Board of Governors," and deposited in the Registrar's Letter-box, on or before Friday evening, 25th inst., and the Candidates are expected to attend before the Board at One o'clock on the following day.

By Order,

JAMES WILSON HUGHES, Registrar.

Board-room, Townsend street, Dublin.  
 12th August, 1871.

# The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 30, 1871.

### CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE X.

*Ovarian Disease continued—Effect of on duration of life—Ovariectomy—Statistics of—Tapping of Cyst—Injection of Cyst—Congestion and Inflammation of Ovary.*

WE will now assume that after having carefully weighed all the symptoms, you have made up your mind that the case you have been called to see is one of ovarian disease; it still however remains for you to consider what its probable course will be, for on this point hinges your future treatment. The most reliable data from which we can form an estimate as to the probable duration of life in the cases of cystic disease of the ovary, are those supplied from the tables of Mr. Stafford Lee. Of 123 cases tabulated by him, nearly a third died within a year, and rather more than one half within two years, from the date at which the first reliable symptoms of the disease were noticed, a duration hardly longer than that of cancer, while but seventeen lived for nine years or upwards, of these seventeen one survived for fifty years. From these tables we may fairly assume that the duration of life in cases of the disease under consideration is unlikely on an average to exceed three or four years. As a rule you may consider that the chance of life being prolonged is in an inverse ratio to the rapidity of the growth of the tumour, for if this be rapid, the patient will speedily be worn out and die,

exhausted no less by the effects of the disease, than by the distress caused by the size of the tumour itself, even should no inter-current attack carry her off after a brief illness.

The simple unilocular form seldom becomes dangerous to life, till the tumour by its great size interferes with respiration and by its pressure impedes the abdominal viscera in the due performance of their functions. When this stage is reached if with the view of relieving the patient's sufferings we have recourse to tapping, we may actually accelerate the fatal termination of the case. The drain on the system caused by the refilling of the sac, increasing the previously existing exhaustion.

The rupture of a cyst is another possible cause of death, this seems to be more likely to happen in the multilocular than in the unilocular tumour, but it certainly is not of very frequent occurrence, in all these cases there is a great proneness to inflammation of the abdominal and even thoracic viscera, and an attack which would in others be of no importance, becomes when supervening in the patient suffering from ovarian dropsy, a very serious matter, and therefore not a few die of disease not directly connected with the original malady, but which is not the less on that account chargeable with the result.

The certain and speedy death which in the great majority of cases awaits the sufferer from ovarian disease, has decided surgeons to attempt its cure by the extirpation of the diseased organ, the question then, which in each case has to be decided is, will the patient if left alone, have a fair chance of being one of the fortunate twelve who, out of every 100 may be expected to live for ten years or upwards, or one of the eighty-eight who if not operated on must in a third of that time be consigned to their graves. In deciding on this momentous question we should never for one moment lose sight of the fact that there are but two possible terminations to operations for the extirpation of ovarian tumours, the one being perfect recovery, the other speedy death.

The most important element in the calculation undoubtedly is the rapidity with which the tumour is in

creasing in size, for if this be rapid the case must soon terminate fatally. Thus in Dr. Barton's case the circumference of the abdomen increased four and a half inches in one month, this patient we may say with almost positive certainty, would have died under any circumstances in a very brief period, and therefore the operation was called for, but if the increase be very slow, we should hesitate before sanctioning it. Again the state of the patient's health will materially influence your judgment, if it be good, and *that she* seems to suffer only from the ordinary effects caused by the presence of a large tumour in the abdomen, she will be in the most favourable state for the operation. I am convinced that the state of health frequently accounts for the results which follow its performance. The two cases I am specially calling your attention to exemplify this, neither were unhealthy women, but the one was in a weakly condition and looked delicate, while the other was in very good general health, she as you have just had an opportunity of seeing made a most excellent recovery, while in the former peritonitis supervened and rapidly proved fatal; a difference in result which can only be accounted for by the supposition that the state of this patient's health predisposed to the occurrence of inflammation. The unfavourable termination in this case influenced me in advising that the operation should be performed at once on the other, and that it should not be deferred till the increasing size of the tumour rendered it more urgent, for I believed that the chances of her recovery were greater now than they would be by-and-by when the progress of the disease must have more or less undermined her health. An opinion which I am happy to say the result has verified. If the patient be suffering from any other organic disease, ovariectomy is hardly justifiable, it would however be impossible to lay down an exact rule on this point. The presence of firm and extensive adhesions greatly increase the risk of an unfavourable result; indeed when the adhesions between the surface of the tumour and the surrounding parts are very intimate the operation nearly invariably terminating fatally, but the diagnosis of adhesions is very difficult, I may almost say impossible to make. By grasping the integuments over the most prominent parts of the tumour and raising them up, and by endeavouring by careful manipulation to make them glide over its surface, a fair estimate may be formed as to whether they exist anteriorly or not, but we have no means of ascertaining what may be the condition of the tumour posteriorly, we are therefore necessarily to a great degree in ignorance on this point. The obscure or repeated occurrence of attacks of sharp pain are however of importance, if the patient has not suffered much, extensive adhesions are not likely to be met with, but if paroxysms of pain have been frequently experienced, we may with confidence anticipate that adhesions exist.

The simpler the tumour is, the greater chance there exists of a favourable termination, and the greater amount of solid material the less hopeful is the case, you may take it as an established rule that the further the tumour departs from the true cystic type the more unfavourable the prognosis becomes. I am always unwilling to sanction the operation of ovariectomy where the tumour is evidently nearly altogether solid.

But even under the most favourable circumstances the mortality in cases of ovariectomy is great; in the tables of results appended to the edition of Kiwisch's work "On Diseases of the Ovaries," translated by Mr. Clay, of Birmingham, himself a successful operator, the results of 537 cases are recorded, 212 as successful, and 183 as terminating fatally, which may be considered as implying that fifty-three per cent. recovered and forty-seven per cent. died; but in the large number 142 cases the operation had to be abandoned, either from the adhesions being too intimate to permit of the tumour being removed, from the disease being discovered to be extra ovarian, or from partial excision only having been

effected. Of these fifty-five died, and this number must, in order to make the estimate as nearly as possible accurate, be added to the 183 fatal cases already mentioned. We are then to deduct from the 537 recorded cases eighty-seven in which the operation was commenced but not carried out, but who nevertheless survived, this leaves 450 to be accounted for, of these 212 were perfectly successful, 238 terminated fatally, showing that nearly fifty-five per cent. of the cases operated on terminated fatally.

But though I quote these statistics and have analysed them for you, you must not accept them as being a fair index of the results of the operation at the present time for the mortality has steadily decreased during the ten years which have elapsed since these tables were published. The errors in diagnosis are now comparatively few, cases unsuitable for operation are rejected, while it is becoming rare to hear of the operation having to be abandoned. Still making every allowance for improved diagnosis, and for greater care in the selection of cases, I do not think we can hope to raise the percentage of recoveries permanently above sixty-five per cent. I am aware that a higher estimate than this of the success of the operation is made by others. Thus Dr. Graily Hewitt states that the recoveries are now from sixty-five to seventy-five per cent.\* perhaps this may be true if errors in diagnosis be omitted, but this I consider it would be wrong to do. I am far from wishing to discourage the operation in suitable cases, and am strongly of opinion that if greater discrimination in selection be used, if the operation be performed earlier and in patients free from symptoms of other diseases, that the results will be still more favourable, nor do I wish to overlook the fact that even if only sixty per cent. of our operations prove successful, we restore to health more than fifty women out of each 100 cases, who would have died in about three years, and this after allowing for the full proportion, who if not treated at all would have lived for a comparatively long period.

I have hitherto spoken only of excision of the diseased ovary an operation which though long known has only been extensively practised within the last few years; but tapping the cyst has been frequently performed both as a palliative measure and also as the first step towards a radical cure. With the former view it is practised when ever the distension of the abdomen is so great as to interfere with respiration. Under such circumstances it is always justifiable, but it is often productive of but very temporary relief, and sometimes only aggravates the patient's condition, for if the cyst falls rapidly again as it generally does, the secretion of such a large quantity of fluid further weakens the already debilitated patient, and moreover tapping is sometimes followed by the rapid growth of other cysts, which seem to have lain indolent previously, their development having been apparently retarded by the pressure exercised on them by the fluid. Inflammation too may supervene and terminate fatally, and lastly bleeding of an alarming character has been known to occur occasioned by the trocar wounding a large vessel. This may take place either into the cyst or into the abdominal cavity, but even where no accident occurs alarming prostration and vomiting have followed on the

\* Since this Lecture was delivered, Mr. Spencer Wells read before the Royal Medical and Chirurgical Society, a paper giving the particulars of his fourth series of one hundred cases of ovariectomy. Of 100 cases in which the operation was completed, seventy-eight recovered, twenty-two died, and thirteen other cases in which the operation was commenced but not completed, or exploratory incisions only made, seven recovered, six died. He shows that the mortality after ovariectomy is in his practice steadily diminishing, of his first 100 cases, thirty-four died, of his second 100, twenty-eight died, of his third 100, twenty-three died, of his fourth 100, twenty-two died, in his private practice he has of late lost but fourteen per cent. This is indeed as it was termed by Dr. West "a splendid success," still I cannot but feel that no small portion of this success is due not only to the dexterity of the operator, but to the skill which he has exhibited in selecting suitable, and rejecting unsuitable cases, a dexterity and skill which all cannot hope to attain, and I fear that the average of all the operations undertaken in Great Britain, will still show a considerably higher mortality than that here recorded.

evacuation of the cyst and in not a few cases has fatal peritonitis ensued, so that the operation simple as it is, is not free from danger. According to Kiwisch of 130 cases of tapping twenty-two died in a few hours or days, twenty-five more died within six months, and he concludes by stating his conviction that all these 130 patients had their lives shortened by the operation.

There have been cases no doubt recorded in which after tapping the cyst has shrivelled up and a permanent cure resulted, but they have been of such very rare occurrence as to hold out little inducement to us to follow the practice, and indeed I am not inclined to advise you to perform the operation of tapping except when compelled to do so as a palliative measure.

Dr. West advises that the operation of ovariectomy should not be performed till the cyst has been tapped. I cannot however concur with him on this point, but I admit that when the cyst is emptied and during the process of refilling its relations to the surrounding parts can be more readily made out, and also that the presence or absence of adhesions may perhaps be ascertained. Tapping also informs us whether the contents of the cyst be viscid or aqueous, whether the tumour be unilocular or multilocular, and may perhaps enable us to decide what amount of solid matter is present. In obscure cases therefore, it is sometimes advisable to tap for the purpose of aiding us in forming our diagnosis.

When for any reason you decide on tapping an ovarian cyst I recommend you to have your patient in bed, and to let her lie on her right side the abdomen being brought well over the edge of the bed. It is advisable to have a bandage round the patient as is usual in tapping for ascites, which is gradually but not unduly tightened as the cyst is emptied. It is better to use a moderately large trocar. Mr. Clay recommends a curved one. It is usual also to have an India-rubber tube attached to the canula as suggested by Mr. Spencer Wells, through which the fluid escapes into a vessel placed to receive it; should however the contents of the sac be viscid this adds to the difficulty of its escape. If the canula becomes plugged it will be necessary to pass a flexible catheter through it for the purpose of clearing the instrument, a matter sometimes of some difficulty. After a cyst has been emptied a moderately tight bandage should be kept round the abdomen and perfect rest enjoined for some days.

Tapping when performed with the view to a radical cure is only preliminary to injecting the cyst with some stimulating fluid — iodine being that usually preferred — the chief objection to the practice being that it is only suitable to cases in which the cyst is single, for if the tumour be multilocular no benefit is likely to follow. The results are under any circumstances very uncertain, sometimes none whatever have followed, while in others the effects were most marked — prostration, vomiting, and inflammatory symptoms — occasionally resulting in a cure of the disease, but sometimes terminating in death. The operation from its uncertain and sometimes fatal results is now seldom performed. I have not had any personal experience of it.

You must have inferred from what I have said that medical treatment is useless in cases of ovarian dropsy excepting so far as the judicious administration of tonics is concerned, and trust none of you will ever be guilty of the folly, to use no harsher expression, of salivating or blistering any patient you may meet with who is suffering from this disease.

I have hitherto spoken only of cystic disease of the ovaries because it is by far the most common as well as most important form of disease to which these organs are liable, but solid tumours of the ovary are also occasionally though very rarely met with. I have never seen an example of this form of disease. Cancer too may attack these glands. I need hardly add that when this occurs the case is beyond the reach of treatment. In addition to these affections which involve change in structure the ovary may be attacked by inflammation, acute inflamma-

tion of the gland is very rare, but chronic inflammation or at least congestion is common enough. To this cause we may probably attribute many of the cases of left-side pain so invariably present in women who are suffering from any form of uterine disease. This pain which is aggravated by pressure or by exercise generally shoots down along the inside of the thigh; in severe cases nausea is sometimes complained of, and even vomiting may be present. The left ovary is the one by far the most frequently engaged; why this should be so, I am quite unable to say, but it is a notable fact which probably you have all observed. Menstruation is occasionally affected, sometimes becoming scanty and attended with pain, but on the other hand I am satisfied that a condition of ovarian irritation short of actual inflammation but in which there is probably a certain amount of congestion present, is a not infrequent cause of menorrhagia. If from the occurrence of the symptoms enumerated you come to the conclusion that inflammation or congestion of the ovary exists, you will best relieve that condition by the application of a few leeches over the seat of the pain, by the exhibition of mild cathartics, and of full doses of the bromides of ammonium and potassium, and subsequently by blistering. We had a good example of chronic inflammation of the ovary in a young woman recently in the medical ward whose prominent symptom was vomiting. I shall have to refer to her case again; at present I can only add that after the application of three or four leeches the vomiting which had been persistent for weeks was temporarily checked.

You must not however suppose that every case of pain in the ovarian region is necessarily due to inflammation; in by far the majority of these cases it is merely sympathetic and is kept up by the existence of some uterine ailment.

Subacute inflammation of the ovary is not of itself likely to be serious, but the constant pain which the patient suffers is very wearing, and exposure to cold or other causes may at any time aggravate it and cause serious symptoms to arise from the inflammation extending to the peritoneum and therefore the affection should never be looked upon as being of no importance.

In many cases of left-side pain depending on ovarian congestion, or irritation, I have found great benefit to follow the inunction twice a day over the affected part, of an ointment composed of equal parts of veratria ointment and of the ointment of the iodide of potassium, to which in some cases I add a smaller proportion of the unguentum cantharidis.

#### CASE OF ATRESIA VAGINÆ, SUCCESSFULLY OPERATED UPON

By MR. BAKER BROWN, F.R.C.S. (Exam.)

(Reported by W. R. O'CONNOR, House Surgeon.)

M. D., when eleven years old came under the care of Dr. Dowsland, of Weavertiorpe, Yorkshire, suffering from pain in the abdomen and back. In a letter received from this gentleman, he states that he found the vagina entirely occluded, and the uterus distended. Dr. Wright, of Malton, who was consulted about the case, made an unsuccessful attempt to relieve the patient by operating per vaginam. She was then sent to Leeds under the care of the late Mr. T. Teale, and he attempted a similar operation, which was again unsuccessful. She then, at thirteen years of age, became the patient of Mr. Baker Brown, and he punctured the uterus per rectum, relief was afforded, and she menstruated for a few months. The opening closed, and Mr. Brown repeated the operation, and menstruation occurred regularly for five months; the opening again became obliterated, and Mr. Brown again operated, this time the bladder was accidentally punctured. A canula was retained in the rectal opening for eleven weeks, after this operation the patient menstruated regu-

larly for seven years through the vesical and rectal openings. Menstruation ceased for some months, during which time the passage became closed, the menses reappeared and escaped per rectum and per vesicam with great pain, they ceased again, and at their next appearance the openings were too firmly closed to allow of their escape. Mr. Brown received her under his care again in March, 1871, and finding on examination of the parts, an increase in the tissues, determined on trying to make an artificial vagina. On March 30th, in presence of Dr. Routh, Dr. Rogers, Dr. Webb, of Cincinnati, and several other medical men, the patient being under chloroform, Mr. Brown dissected up to the uterus between the bladder and rectum, and punctured it with a trochar and canula, the canula was retained for seven days. An Ellis's drainage tube was then substituted, a sea-tangle tent being at the same time introduced and changed every day, the drainage tube was kept in for twelve days, after this sea-tangle tents were used, the vagina being syringed and the tents changed every other day up to the 2nd of June, when several were introduced together, and the passage dilated to a much greater extent. One of Marion Sims' glass tubes for dilating the vagina was now introduced, and has been worn since. She has menstruated twice lately without pain *per vaginam*.

The undersigned gentlemen examined her on the 20th of July, and state the condition in which they found the part. "There is a capacious vagina about three inches long, and about one and a half inches in diameter, lined by mucous membrane, tapering at inner end conically where the uterus is to be felt, but no positive os can be detected, though there must be a fistulous opening to it as she menstruates from it regularly and without pain."

(Signed) C. H. J. ROUTH.

of San Francisco.

## THE PHARMACEUTICAL CONFERENCE.

President—MR. W. W. STODDART.

THE Conference was held this year at Edinburgh, during the meeting of the British Association for the Advancement of Science, of which we have given a full report.

The PRESIDENT opened the proceedings with an

### INAUGURAL ADDRESS,

in which he passed in review some of the most important announcements of the past year in reference to chemistry and pharmacy.

In the course of the address he said :—

Oxygen, in its ordinary condition, and without the aid of moisture and heat, could not destroy the pestilent gases and organisms that abound in our crowded streets and courts; but, in its allotropic form, no sooner does it come in contact with the deadly impurities from our lungs and skin, or the emanations arising from our unnatural mode of living, than it immediately attacks the evil by destroying its very constitution, and prevents its poisonous influence on our health and comfort.

Can it be right, therefore, that so many of us should be from day to day in the midst of the various ozone-producing agents and recommending their use, and yet all the while not caring to know the why and wherefore of their friendly reactions?

Perhaps of all the discoveries which modern chemistry has introduced, the most marvellous are the methods of analysis and synthesis of the organic bases.

Who could have supposed that there was the least relationship between two such dissimilar bodies as cinchona bark and gas tar; nay, more, that they should give rise to the same substance? Yet so it seems to be.

When either morphia or codeia is treated with hydrochloric acid under pressure, an entirely new base is produced, called by its discoverer apomorpha ( $C_{17}H_{17}NO_2$ ), and although it only chemically differs from morphia by the abstraction of the elements of water, it has the most opposite properties.

Apomorpha is remarkable for its powerful emetic qualities and unstable nature. The chloride, which is the salt most commonly used, is white and crystalline. Its freedom from all irritant properties renders it a valuable hypodermic agent. Only one-fifth of a grain by the mouth or one-tenth by subcutaneous injection acts with greater rapidity than any other emetic; indeed, it is the only one capable of being administered hypodermically.

When codeia is acted upon under pressure by an excess of hydrochloric acid, a new base is separated, which the discoverers, Messrs. Matthiessen and Wright, called chlorocodide ( $C_{18}H_{20}NO_2$ ).

A further re-action then takes place, and the chlorocodide splits up into methyl chloride and apomorpha.

So that the curious fact appeared that codeia only differed from morphia by containing one equivalent more of methyl. Although, however, they obtained apomorpha from codeia, they were unable to reconvert apomorpha into morphia, and thus form morphia directly from codeia.

Dr. Hugo Schiff, of Florence, has announced that he has succeeded in artificially producing conia, the active principle in *Conium maculatum*. He says that when butyraldehyd is acted upon by alcoholic ammonia, dibutyraldin is formed.

By the dry distillation of the latter, conia, among other products, is eliminated, and may at once be recognised by its peculiar odour.

The President alluded to the new cinchona alkaloid discovered by Mr. Howard, the properties of chloral, the anaesthetics, the fluorescence of oil of peppermint, the chemistry of ammonium carbonate, Dr. Atfield's proposal for an improved nomenclature, and to the year's work.

After some business was disposed of, the reading of papers was proceeded with.

Among the papers read were :—“On Oxidation Products of Essential Oil of Orange-peel,” by Dr. Wright. “A Report on Chloral,” by Mr. Mason. “A paper on Chloral,” by Mr. P. Muir. “A paper on *Rhamnus triangula*,” by Mr. H. C. Baildon. “The Compound Iron Mixture of the Pharmacopoeia,” by Mr. A. E. Staples. “Report on the Permanganate of Potassium of Pharmacy,” by Professor Allen. “Blistering Flies in Hydrophobia,” by Mr. Groves. “The Crystalline Principles in Aloes,” by Professor Fluckiger. “Notes on Aloes, with reference chiefly to the Cathartic Qualities of Aloin,” by Messrs. T. and H. Smith, Duke street, Edinburgh. “On Linseed and Linseed Meal,” by Mr. Thomas Greenish, F.C.S. “The Tincture Press,” by Mr. C. A. Staples. “The Wild Rue—*Semen harnale*,” by Professor Fluckiger; and a “Method of obtaining Distilled Water economically,” by Mr. Staples.

Professor WRIGHT then read the following paper :—

### NEW DERIVATIVES FROM CODEIA.

BY CHARLES R. A. WRIGHT, D.S.C.,  
Lecturer on Chemistry in St. Mary's Hospital Medical School.

By the action of hydrobromic acid (48 per cent. H Br) on codeia at 100°F., there is produced firstly a base containing the elements of codeia, where OH is replaced by Br; and by a further action to other bases, one containing one atom

of oxygen less than codeia, the other having the composition of four molecules of codeia coalesced together, one of the 84 hydrogen atoms in the product being replaced by Br.

|                        |                           |
|------------------------|---------------------------|
| Codeia . . . . .       | $C_{18}H_{21}NO_3$        |
| Bromocodeide . . . .   | $C_{18}H_{20}BrNO_2$      |
| Deoxycodeia . . . . .  | $C_{18}H_{21}NO_2$        |
| Bromotetracodeia . . . | $C_{72}H_{83}BrN_4O_{12}$ |

The last base is almost insoluble in ether, whereby it can be separated from the other two, which are readily soluble in that menstruum.

The further action of hydrobromic acid on the above bodies gives rise to the substitution of H for  $CH_3$  in them, the following substances being obtainable by this means:—

|                             |                           |
|-----------------------------|---------------------------|
| Deoxymorphia . . . . .      | $C_{17}H_{19}NO_2$        |
| Bromo-dicodeia-dimorphia .  | $C_{70}H_{79}BrN_4O_{12}$ |
| Bromotetramorphia . . . . . | $C_{68}H_{75}BrN_4O_{12}$ |

When treated with strong hydrochloric acid at the ordinary temperature, the bromine in the tetra-bases described above is replaced by chlorine. Thus, the following bodies have been analysed (*i.e.*, their salts):—

|                               |                           |
|-------------------------------|---------------------------|
| Chlorotetracodeia . . . . .   | $C_{72}H_{83}ClN_4O_{12}$ |
| Chloro-dicodeia-dimorphia . . | $C_{70}H_{79}ClN_4O_{12}$ |
| Chlorotetramorphia . . . . .  | $C_{68}H_{75}ClN_4O_{12}$ |

The physiological action of the above bodies does not appear to be very marked. Dr. Michael Foster finds that the above bodies produce in cats a peculiar excitement of the nervous system and paralysis of inhibitory fibres of the pneumogastric. Deoxycodeia and deoxymorphia salts produce also convulsions of an epileptic character. In case these properties should ever cause the substances to be used in medicine, probably a pill would be the most convenient form of exhibition as the sparing solubility of their salts in water, and the comparatively large dose requisite, would preclude the use of hypodermic injections.

On treating codeia with hydriodic acid (55 per cent. H<sub>1</sub>) and a sufficiency of phosphorus, methyl iodide is evolved, and a series of products obtained which much resemble one another in physical character, being amorphous, brittle or tarry bodies. If the action takes place at 100°, 110°–115°, or at higher temperatures up to 130°, the following three substances appear to be produced:—

|   |              |
|---|--------------|
| I. $C_{68}H_{86}I_2N_4O_{12}, 4HI$ . . . . .  | at 100°      |
| II. $C_{68}H_{82}I_2N_4O_{10}, 4HI$ . . . . . | at 110°–115° |
| III. $C_{68}H_{82}I_2N_4O_6, 4HI$ . . . . .   | up to 130°   |

On boiling up with water, these bodies part with the elements of hydriodic acid, and either lose or take up those of water. Thus, the following substances have been procured:—

|   |                     |
|---|---------------------|
| IV. $C_{68}H_{81}IN_4O_{10}, 4HI$ . . . . . | from II.            |
| V. $C_{68}H_{80}N_4O_{10}, 4HI$ . . . . .   | from both I and II. |
| VI. $C_{68}H_{88}N_4O_{10}, 4HI$ . . . . .  | from III.           |

A similar reaction also appears to take place by precipitating the solutions of I., II., III., with sodium carbonate; in this way the free bases of the compounds IV. and V. have been obtained from I.

Lastly, on treating with hydriodic acid the compounds IV., V., VI., the elements of hydriodic acid and water are taken up, forming compounds not losing the added water even by long-continued exposure to a temperature of 100°. Thus—

|   |                      |
|---|----------------------|
| VII. $C_{68}H_{107}I_3N_4O_{22}, 4HI$ . . . . . | from both IV. and V. |
| VIII. $C_{68}H_{89}IN_4O_{10}, 4HI$ . . . . .   | from VI.             |

While, on treating I. with hydriodic acid and phosphorus, the following compound (containing the elements of hydriodic acid and water more than III.) was produced:—

|  |
|--|
| IX. $C_{68}H_{103}I_3N_4O_{16}, 4HI$ . . . . . |
|--|

The physiological action of the foregoing compounds has not yet been examined particularly, but it does not appear to be marked, no ill effects having been observed while working with the bodies. Names have not yet been given to these substances, owing to their complexity.

The codeia used in the experiments briefly described above formed part of a large supply exceeding twenty ounces, most liberally presented for the purpose by the eminent manufacturing chemists, Messrs. Macfarlane, of Edinburgh.

The PRESIDENT said that the subject had been very clearly explained by Professor Wright, and he considered it was a paper well worthy of being read at the Conference.

MR. BRADY said he would like to make one remark about Professor Wright's paper, not that he was going to discuss any point, but as it bore on a little experience he had had, it came with a peculiar force in Edinburgh, which was very much the seat of the morphia manufacture, but it was not so much that as the liberality of the manufacturers of the morphia alkaloids in helping scientific men with materials. Some years ago, when Mr. Deane and himself were making experiments in the morphia alkaloids, in an experimental sense, Messrs. T. and H. Smith and Messrs. Macfarlane assisted them by furnishing materials; and he could not sit there without testifying to their extreme kindness, not in matters of business only, but also to their interest in scientific research.

Professor WRIGHT said that Mr. Brady had called to his mind what he ought to have mentioned before, though it would be seen that it had not been overlooked in his paper. He most sincerely returned thanks to the Messrs. Macfarlane, not only for a supply of codeia, but many other alkaloids. The codeia given by Messrs. Macfarlane weighed upwards of twenty ounces.

## THE THIRTY-NINTH ANNUAL MEETING

OF THE

## BRITISH MEDICAL ASSOCIATION,

Held at Plymouth, August 8th, 9th, 10th, and 11th, 1871.

President: JOHN WHIPPLE, Esq., F.R.C.S.

DR. JULIUS ALTHAUS read a paper "On Paralysis of the Bladder, and its Treatment by the Constant Galvanic Current." After referring to some important researches on the physiology of micturition lately made by Professor Eudge, of Griefswald, he entered into the pathology of paralysis of the bladder. He eliminates from this affection all cases of mere atony of the viscus from over-distension owing to organic obstructions, such as stricture of the urethra and hypertrophied prostate, and other causes; and likewise all cases of incontinence of the urine which is generally ascribed to paralysis of the sphincter vesicæ. Real paralysis of the bladder is, according to Dr. Althaus, only observed (*a*) when the conduction of nervous influence from the pedunculus cerebri to the bladder is interrupted; (*b*) when the lower part of the lumbar portion of the spinal cord is diseased; and (*c*) when the normal excitability of the motor or sentient nerves of the bladder is pathologically altered without any central affection being present; most cases of this latter class being of the kind termed reflex or inhibitory paralysis. After reviewing the treatment generally adopted for this condition, the author expresses his opinion that, both in efficacy and quickness of action, the constant galvanic current properly applied is superior to all other remedies which are used for this affection. He then describes the best mode of applying the current in such cases, and winds up by relating three cases illustrative of the different varieties of the complaint. One of these was owing to syphilitic disease of the pedunculus cerebri; another occurred in a hysterical patient; and the third arose from disease of the lumbar cord. In all these cases the paralysed bladder recovered rapidly under the influence of the constant galvanic current.

MR. FURNEAUX JORDAN read a paper "On the Extension of Inflammation from the Epididymis to the Urethra." Inflammation of the prostatic urethra from any cause (injuries, operations, foreign bodies, urinary obstructions, or adjacent inflammations), may, he said, extend to the epididymis. It would be an original discovery to find any variety of prostatic inflammation which might not run by continuity along the submucous connective tissue of the vas deferens. He was not aware that anyone had observed the converse of this. He had recently watched a case in which inflammation unmistakably travelled from the epididymis to the urethra. A married man, free from disease and the history of disease, suffered from the effects of a severe blow on the scrotum. On the subsidence of scrotal swelling, the left epididymis was found to be enlarged, painful, and tender. The next day the adjacent

portion of the vas deferens was tender, and swollen to the size of a goose's quill to near the inguinal ring. The following day the swelling of the cord extended into the ring. A few days later a slight urethral discharge appeared, and all the symptoms of a mild urethritis. Mr. Jordan believed any new fact to be of value which would help to explain urethral discharges.

Dr. VICTOR JAGIELSKI read a paper "On Cow's Milk Koumiss." He said that koumiss is a pure animal milk in a state of fermentation. In its composition it combines all the requirements of a wholesome nutrition of the human body; while certain products of the fermentation add to it important therapeutic properties. All animal milks are convertible into koumiss, and the general qualitative composition of the products is the same for all. In all, the act of fermentation sets free the casein, albumen, and butter in a highly attenuated form, and develops alcohol and carbonic and lactic acids, together, according to Morfit, with certain fragrant volatile compounds. Once started, it continues until all the lactose of the milk has been transformed, and this transmutation is more rapid in proportion to the rise in the temperature of the air. Dr. Jagielski distinguishes the three gradations thus formed, according to their respective physiological effects; but though each may have a specific application, the general properties are retained by all. No. 1. This is the freshly made koumiss, with the minimum of the products of fermentation. In three or five days it becomes—No. 2, which is more acidulous than sweet, and so sparkling that it requires to be drawn from the bottle through a tap. In ten to fifteen days it has changed into—No. 3, when the fermentation is more developed than in No. 2, and extends to the maximum with time. Consequently the taste is acid, and the koumiss rushes through the tap as a rich, creamy, foaming liquor. After quoting many distinguished European and American authorities in its favour, the author noted some of the favourable results of his own professional experience with the use of koumiss in cases of constipation, impaired digestion, debility, chronic bronchitis, consumption, diarrhoea, in the adynamic stage of febrile diseases, after confinements, operations, in diabetes, &c. In conclusion he urged a thorough trial of it in both hospital and private practice, believing that, though it is not a specific for any disease, it merits the most serious consideration as a most benign medicinal agent.

Dr. PROTHEROE SMITH read a paper on "A Successful Method of Treating certain Cases of Dysmenorrhœa and Sterility." After giving the pathology of obstructive dysmenorrhœa, with the usual mode of treatment, he called attention to that of dilatation by bougies, suggested by Dr. Mackintosh, and the modification of it by Sir James Simpson, and his operation of incision of the cervix by the hysterotome. Dr. Protheroe Smith's experience having suggested a doubt of the advantage of this practice. To overcome the stricture of the os internum, Dr. P. Smith uses extension force by means of his uterine dilator. And to restore the os tince to its natural form, per speculum, he incises it laterally at the commissures of the labia.

Dr. SWAYNE read a paper "On the Treatment of Hæmorrhage arising from the Retention of the Secundinæ after Abortion." Treating chiefly of abortions in the third, fourth, and fifth months, he pointed out their dangers from special liability to retention of the secundinæ, and consequent hæmorrhage and septicæmia. Obstetric authorities were divided as to treatment, some favouring an expectant plan, with the use of plugging, ergot, styptics, and disinfectants to obviate hæmorrhage and septicæmia, and others advocating manual interference. He remarked that the plug might sometimes cause an accumulation of blood in the uterine cavity, and showed a pad for preventing this, by making pressure on the fundus uteri. He pointed out the risks of intra-uterine injections, when a large amount of fluid is thrown up with too much force. After remarking that the weight of obstetric evidence in the present day is in favour of manual interference, he stated his concurrence in this view; but that he preferred, instead of using the hand for removing the placenta, to employ an ovum forceps, so modified as to act both as a dilator and an extractor.

Dr. THOS. UNDERHILL read a paper "On the Treatment of certain Cases of Placenta Prævia, and of Post-partum Hæmorrhage." The author was opposed to the maxim so strictly enforced by most authorities, that in cases of "unavoidable" hæmorrhage delivery should not be attempted whilst the patient is in a state of syncope. During that condition the hæmorrhage ceases, the patient is in a state of anæsthesia, and the soft parts are relaxed—these being three desiderata for the

safe and speedy performance of podalic version. By waiting until the circulation is re-established, and consciousness restored, there will be most probably a recurrence of the hæmorrhage, and the patient will have the dread of a formidable operation. Cases were given in support of the practice suggested. In the second part of his paper, Dr. Underhill advocated the view that in cases of post-partum hæmorrhage, should syncope supervene, it was more prudent to remain passive for a time than to resort to hasty measures to restore consciousness. He based his argument upon the fact that, during syncope, the circulation being either languid or altogether suspended, coagula would be more likely to form and occlude the patulous orifices of the vessels than when subjected to the artificial impetus.

Mr. LUND (of Manchester) read a paper "On Antiseptic Surgery." It was argued by the author that antiseptic might be brought about by any means through which the excreta of wounds were protected from putrefactive change, and the surfaces on which they rest preserved from contact with the irritating chemical products thus elaborated. In recent wounds the strict observance of antiseptic saves much constitutional distress, tends to keep the tissues from loss of substance by sloughing ulceration, and the patient's strength by needless suppuration. But in healing-wounds it was admitted that greater time will be often required to complete a perfect cicatrix, although this, when formed, will be more pliable and natural than under other modes of treatment. The claims of many antiseptics were considered, but preference was given to carbolic acid in very weak solution, or in that form of composition which Professor Lister has described as his carbolised muslin, a modification of the antiseptic cerecloth first proposed by Mr. Lund at the meeting of the Association at Leeds in 1869.

Mr. THOMAS LITTLETON read a paper "On the Effects of Submarine Descent of Man, and the Limits to his Capability," containing a comparative consideration of the anatomy of the whale, and an estimate of the probability of man's capability, from a physical point of view, to compete with the whale in diving, as he has successfully with the eagle in balloon ascent.

Dr. MERRYFIELD read a paper "On the Meteorology and Climate of Plymouth." In which he spoke of—1. Distinction between weather and climate. 2. Mean temperature, how found. 3. Hottest and coldest months of the year, time of day of maximum heat, &c. 4. Humidity, as obtained from the hygrometer; uses of wet and dry bulb readings in producing an artificial climate for invalids. 5. Effects of Gulf Stream on S.W. coast. 6. Ranges of temperature. 7. Atmospheric pressure. 8. Prevailing winds. 9. Rainfall; extremes and droughts. 10. Ozone; storms, electrical and atmospheric. 11. Conclusions.

Mr. W. J. SQUARE read a paper "On Loose Cartilages in the Knee-joint, and their removal by Subcutaneous Incision." The first part of the paper contains remarks on the dangers of valvular and direct incision for the removal of loose cartilages from the knee-joint, and a reference to a few cases illustrative of these dangers; next a record of twenty-four consecutive and unselected cases of removal of loose cartilages by subcutaneous incision, without anxiety, let or hindrance; an appeal to the profession to adopt the operation; and lastly, a few remarks on the varieties of loose cartilage, their structure, and origin, illustrated by a series of preparations.

Mr. W. J. SQUARE also read a paper "On the Influence of Nerves in the Repair of Fractures." The paper is founded on a case of simultaneous fracture of the spine, ulna, and femur. The patient survived three weeks. As the fractures were placed under precisely similar circumstances, the difference between the two (femur and ulna) was presumed to be due to the abstraction or otherwise of the influence of nervous centres.

Dr. GEORGE JOHNSON read a paper "On Cholera," in which he maintained that during collapse there is impeded circulation through the lungs, caused by contraction of the minute pulmonary arteries; just as in the arrest of circulation which occurs in acute apnoea. He proceeded to assert that: In the treatment of cholera and choleraic diarrhoea, which is, in fact, cholera in a mild form, the main principle to bear in mind is, that the discharges are essentially curative as is the eruption of small-pox. The discharges are not to be abruptly stopped by opiates. Experience has abundantly proved that this is a pernicious practice. Neither are they to be permitted to accumulate in the alimentary canal. There is one remedy which is almost universally applicable in all forms

and stages of the disease, and that is an abundant supply of cold water to flush the intestinal sewer, and to wash out the poisonous discharges. A copious imbibition of pure cold water will suffice for the cure of most curable cases. Palpation and percussion of the abdomen reveal the fact that there occurs not unfrequently a painful and sometimes a paralyzing over-distension of the bowel by rapidly effused morbid secretion. This, if not promptly relieved, may even go to the extent of causing a fatal obstruction. More especially is this likely to happen when the sensibility of the bowel has been deadened by opium. The plan to prevent and to remove this accumulation is to give some quickly acting yet unirritating evacuant dose. For this purpose, castor-oil is, on the whole, better suited than any other remedy. The objection sometimes raised—that all remedies must be useless, because none are absorbed—obviously does not apply to such a remedy as castor-oil, which, by its merely local action upon the mucous surface, stimulates the bowel to expel its contents. Experience has amply proved the success of the treatment in this and kindred cases of cases. The time to give opium, if at all, is in small doses to soothe the bowel after the expulsion of the poisonous secretions. Opiates are useless, and even dangerous, when the blood is poisoned, or when the bowel contains offensive morbid secretions. Opiates in the early stages of diarrhoea and cholera would be more frequently and decidedly injurious, were it not for the fact that their absorption is prevented by the rapid current of liquid which is being poured from the blood into the alimentary canal; therefore they are quickly expelled, together with the morbid secretions, and they are powerless to arrest the discharges.

DR. ROBERT MARTIN, of Manchester, read a paper intended to show that intemperance is a powerful predisposing cause of cholera. Indigence, overcrowding and filth, are often caused by intemperance, which is, therefore, responsible for outbreaks of disease; but, in addition, Dr. Martin thinks that the poisonous effects of alcoholic liquors directly favour the development of zymotic agents. During the cholera-visitations of 1832, the nurses in the Manchester Cholera Hospital were at first allowed to go home each day at certain intervals. This arrangement gave them the benefit of a certain amount of out-door exercise and change of atmosphere, as well as relieved the tedium of their duties; the mortality, however, amongst them was so great that it was feared that the supply would fail. It was discovered that, with the idea of protecting themselves against the disease, they indulged freely in liquors; they were therefore confined to the hospital, and debarred from obtaining more than a small allowance of alcoholic drink, after which not a single fresh case occurred amongst them. Here we see that, notwithstanding far less favourable hygienic conditions, there was an immunity from cholera attacks when there was a greatly diminished consumption of alcohol. The experience of Dr. French as Medical Officer of Health for Liverpool, was cited in support of this view, and Dr. Martin urged that in taking means for preventing the advent or spread of cholera, the utmost efforts should be used by the authorities for limiting the facilities for procuring intoxicating liquors. When an attack is impending, intemperance ought to be most stringently dealt with. The drunkard is a source of the greatest danger to himself and to the community. The utmost efforts of the authorities, and the most lavish expenditure of funds, may be neutralised by the reckless conduct of a few intemperate persons. Every means ought therefore to be taken in order to prevent drunkenness, and incentives to intemperance should be as far as possible suppressed.

DR. AVELING read a paper on

THE VALUE OF ARSENIC IN MENORRHAGIA AND LEUCORRHOEA.

Its use in some uterine affections was pointed out by Dr. H. Hunt in 1838, but had not received sufficient attention from gynaecologists. Dr. Aveling had been administering it for twelve years in cases of menorrhagia with marked success. Besides the improvement which it effected upon nutrition, respiration, and secretion, he believed it to possess a powerful decongestive action upon all mucous membranes. In all disorders of the uterus having a hyperæmic origin, he confidently recommended the use of arsenic. He administered small doses either in solution or granules, increasing them from time to time, and continuing them for weeks or months, as the necessities of the case might require.

DR. J. HUGHLINGS JACKSON read a paper on

TUMOUR OF THE MIDDLE LOBE OF THE CEREBELLUM.

This case was observed in the London Hospital by the author and by Mr. Stephen Mackenzie. There was found, on *post-mortem* examination, a tumour of the middle lobe of the cerebellum, which had pressed on the corpora quadrigemina and on the veins of Galen. There was also a small tumour of the right corpus albicans. Much fluid was found in the cerebral ventricles, and the horns of the lateral ventricles were greatly dilated. The chief symptoms during life were—(1) enlargement of the head, (2) double optic neuritis, and (3) reeling gait, followed by permanent rigidity of the legs and paroxysms of convulsions somewhat like those of tetanus. These seizures, the author supposed, furnish some evidence in support of the view that the changes in tetanus are in the cerebellum. The author referred to cases of a like kind, and particularly to one by Dr. Gull and to one by Mr. Warren Tay, in which a like diagnosis had been made.

DR. J. F. PAYNE read a paper ON THE NERVOUS ORIGIN OF CERTAIN CUTANEOUS AFFECTIONS.

Certain affections of the skin were more or less generally acknowledged to be governed in their distribution by the distribution of nervous structures, and were therefore presumably due to some abnormal nervous activity. Among these were more especially noticeable herpes, or herpes zoster, and that peculiar local induration of the skin called morphea. In a case of each of these complaints, described in the paper, the cutaneous manifestations were associated with affection of the motor part of the nervous apparatus. In a case of herpes in a child, affecting the right lower extremity, and corresponding to the superficial branches of the anterior crural nerve, the appearance of the eruption was preceded for three days by temporary hemiplegia of the same side. The other case was that of a child suffering from hemiplegia, with some permanent contraction and occasional spasmodic movements of both the upper and lower limb, and in whom part of the skin of the face of the same side was affected with local scleroderma or morphea. The skin of this part was hard and white, neither raised or depressed; and the alteration was thought to be confined to those parts of the integument supplied by the superficial branches of part of the fifth cranial nerve. In both these cases the peripheral nervous affection giving rise to the skin disease appeared to be dependent on some morbid condition—in the one case temporary, in the other chronic, of the nervous centres; and that this explanation might be applicable to other cases.

DR. ARTHUR RANSOME read a paper on

THE RESPIRATORY MOVEMENTS IN MAN.

The paper recorded observations made with Dr. Burdon Sanderson's stetho-cardiograph as to the order of movement of the ribs in ordinary and forced breathing in males and females; and also measurements of the movements of different points in the chest wall, made simultaneously in three planes by means of the author's stetho-metrometer constructed for the purpose. From these measurements conclusions were drawn as to the mode in which the several movements were produced, and variations in the extent of movement in different directions were pointed out in the two sexes at different ages, and in different positions. The influence of various muscular power was shown, and the variety produced by different diseases, especially phthisis, pleurisy, and emphysema.

MR. CHARLES STEELE, F.R.C.S., related a

CASE OF EXCISION OF THE SCAPULA.

Charles Bees, æt. eight, was admitted on April 14th into the Bristol Royal Infirmary, on account of a large swelling upon the right scapula, which had been forming only six weeks, and had enlarged very rapidly during the last fortnight. The tumour covered the whole surface of the scapula except the inferior angle, and encroached over the upper border towards the clavicle; it was firmly adherent to the scapula, most prominent over the spine, and had a highly elastic and, in parts, fluctuating feeling. The child had fallen off in flesh slightly, and looked rather delicate. Mr. Steele made an exploratory incision, and removed a minute portion of the substance, which on microscopic examination showed large, almost square, cells filled with secondary cells. Extirpation of the scapula was decided upon; and, on the 18th, after making a free incision down to the bone through the tumour to confirm diagnosis, Mr. Steele made a free elliptical incision from the upper border to the inferior angle, carefully surrounding the first incision, so as to avoid infiltration. He then slipped the inferior angle of the scapula from under the *latissimus dorsi*,

divided the muscles attached to the posterior and anterior borders, freed the subscapularis muscle from its surroundings, divided all connections of the clavicle and humerus close to those bones, and, by very delicate dissection, cleared the projections of the tumour from their close proximity to the subclavian vessels, &c., The suprascapular, posterior scapular, and subscapular arteries, and one muscular branch, were secured. The forearm was supported across the chest, and a compress of wool applied over the excavated cavity. The tumour had evidently sprung from the bone; it covered its dorsum, infiltrated its tissue, formed a large firm projection on the venter, and had stretched the supraspinatus, infraspinatus and subscapularis muscles as a capsule enclosing it. Recovery steadily progressed till the seventh week; the wound was then nearly healed, the child ate well, had gained in flesh, was able to be up all day and go into the garden and looked well. Two nodules of encephaloid now recurred, and were removed entire, the intercostal muscles being cleaned in doing so. Ten days afterwards, a fresh nodule formed near the spine; and the granulating surface of the wound became so infiltrated that all hope of further removal had to be abandoned. It was some satisfaction to notice that all recurrence of disease was in the lower part and towards the spine. Mr. Steele remarked that this case showed clearly two points: first, that the operation was well borne by the system, and recovered from; and, secondly, that even before cicatrization was complete, a surprising amount of movement existed in the arm. The hand and forearm could be freely used, and the arm drawn well forwards, also extended from the side, and even drawn backwards by the latissimus dorsi muscle. This showed that, had disease not returned, a very useful limb would have resulted.

DR. RAWDON MACNAMARA read an interesting paper on  
THE TREATMENT OF ANEURISM BY COMPRESSION.

Dr. Macnamara's great object was to exhibit the instruments used by Irish surgeons. He thought that compression by instruments was the best, as it could be placed directly on the artery, and the force regulated. Constant pressure was obtained by instruments; whereas, if digital compression were relied upon, there must be occasional cessations of pressure by the students. He knew that if the pressure of more than nine pounds were required to stop the pulsation, the patient must be reduced.

MR. WILLIAM MACCORMAC, F.R.C.S., read some  
NOTES ON AMBULANCES.

Mr. MacCormac explained that he was called upon to undertake the charge and treatment of upwards of one thousand cases of gunshot wound within the space of twenty-four hours. The operations were chiefly excision of the shoulder and elbow, including the hip and shoulder joints; and the result showed the impracticability of following the wholesale lessons of that conservative surgery practised in British hospitals. He endorsed the importance of primary rather than secondary amputations, and was sorry that in Plymouth, where Mr. W. P. Swain had earned a high reputation for his work on "Excision of the Knee-joint," he could say nothing in favour of this operation. In gun-shot wounds received in action, it was wholly inapplicable. A very distinguished German surgeon performed it thirty-six times; thirty-five of the patients died soon, and the thirty-sixth required amputation of the thigh.

MR. BERKELEY HILL described  
A NEW STRICTURE-DILATOR.

The instrument was described as operating on the principle of Pèrèze's, Holt's and Richardson's. The two halves of a split sound, equal when in juxtaposition to the calibre of a No. 2 or No. 3 catheter, could be separated by thrusting between them a segment of a cone fixed to a slender stem, until they occupied a space equal to a No. 12 catheter. The dilation might be carried on to No. 14 or No. 16 of Weiss's scale. The advantages said to be possessed by the instrument were, simplicity and cheapness of construction; absence of necessity for a central guide; and diminution of resistance.

DR. WM. R. E. SMART, C.B., Inspector-General Royal Navy, read a paper

ON INJURIES OF THE AXILLARY ARTERY OCCURRING IN  
ARTILLERY PRACTICE.

Three cases of injury of the axillary artery resulting in gangrene, caused by violent throwing back of the upper extremity when explosions take place in the act of loading cannon, were cited to show that this peculiar injury occurred when the explosive force had not been of the highest degree. Dr. Smart had never known an injury to occur at the shoulder where the

hand had been blown away. The proper treatment at the seat of vascular injury was, by cold or other means, to ensure early coagulation and fibrination of the clot, which happened successfully in two of the cases cited, and not to delay amputation at the middle of the upper arm as soon as gangrene had begun at the fingers.

DR. T. E. BEATTY related a case of  
FIBRO-CYSTIC DISEASE OF THE UTERUS,  
and showed a recent specimen which exhibited the mode of formation and growth of this important complication of fibroid disease. The case had been tapped three times, and dark-coloured albuminous fluid had been removed by the *aspirateur* at each operation. When Dr. Beatty saw the patient, which was a week before her death, he found the abdomen occupied by an uniform tumour, very much resembling a gravid uterus, at the eighth month of pregnancy, in size and shape. On pressing deeply, distinct fluctuation could be felt, and the walls of the cavity gave the impression of being thicker and more fleshy than those found in ovarian dropsy. The uterus, when examined by the finger and sound, appeared healthy, and of the normal size; but it was fixed in its position, and could not be moved. Dr. Beatty declared his opinion that the case was one of fibro-cystic disease of the uterus. The third tapping was performed after this, and the woman died of peritonitis in a few days. A *post-mortem* examination had verified the opinion that had been given. A case of removal of a large fibroid from the fundus of the uterus by operation, by Mr. Spencer Wells, in which the woman recovered, was mentioned, and Dr. Beatty said that a similar operation, if performed upon the subject of the case just detailed, might have been followed by success; but no one could have foretold the smallness of the connection between the tumour and the uterus during life.

DR. R. W. CHICHTON read a paper on  
THE VALUE OF THE SULPHATE OF IRON AS A LOCAL APPLI-  
CATION IN PHLEGMASIA DOLENS.

This method of treatment was first adopted by the author many years ago, from the great success reported by Velpeau from its use locally in erysipelas. It had been employed exclusively in that form of phlegmasia dolens commencing at the calf of the leg and extending upwards to the groin, where the veins are chiefly involved. It had been applied as a lotion (twenty or thirty grains to one ounce of water), as hot as the patient could comfortably bear it, generally by means of spongio-piline. All the cases so treated had made good and rapid recoveries, contrasting favourably with cases formerly treated by leeching and hot fomentations. Mariated tincture of iron was, at the same time, given in large doses. The same method of treatment was suggested in other cases of phlebitis. The action of these remedies was referred to their power of controlling vascular dilatation, and also to their antiseptic powers.

DR. T. E. BEATTY read a paper on  
THE RADICAL CURE OF RETROFLEXION OF THE UTERUS.

The object of the paper was to show that a vaginal pessary might give relief by supporting the entire uterus; but that it could not effect the restoration of the natural shape of the organ by obliterating the vicious bend which it had acquired. That could only be secured by straightening the uterus by means of the sound, and keeping it straight by a stem passed into its cavity, and retained there by some means that would not confine the uterus in a fixed position, but would leave it free to move in pelvis according to position of the patient or the extent to which the rectum or bladder were distended.

PROFESSOR LISTER, F.R.S., delivered the Address on Surgery, and took for his subject

THE ANTISEPTIC SYSTEM OF TREATMENT OF DISEASE.

A system of which he is the greatest and most able of living champions. He defined its theory very fully, quoted the opinions, and mentioned many of the experienced modes, including those of Porteus, which are familiar to most of us, in favour of its advantages. Professor Lister dwelt for a considerable period of time on the great beauty and many scientific advantages derivable from Professor Tyndall's recent experiments, passed in review most of the well-known substances employed in the antiseptic treatment of disease, and their action, as employed by himself. He earnestly besought the portion of his audience engaged in surgical practice to give the facts narrated by him their careful consideration; "and if you think," says Professor Lister, "that the interpretation I have given a sound one, do not let any statements—whether in books or in journals—shake your belief in the truth that putrefaction under atmospheric influence, as it occurs in sur-

gical practice, is due to particles of dust, ever present in the atmosphere, that surrounds our patients endowed with wonderful chemical energy and power of self-propagation, yet, happily, readily deprived of energy by agents that may be employed for the purpose, without inflicting serious injury upon the human tissues. With this as your guiding principle you will be successful with the antiseptic system of treatment, but without it whatever theory you adopt you will ever be walking in the dark, and therefore ever liable to stumble." The learned lecturer minutely detailed the advantages of antiseptic lotions or sprays, and the application of Dr. Richardson's ether spray apparatus for their distribution; also showed the advantages of the antiseptic cat-gut system for securing vessels, and exhibited many ingenious contrivances used in his treatment of disease. He gave a most interesting history of some cases that had been under his care, and showed the amount of success which followed. He also exhibited specimens of cancellated bone removed from patients whilst under antiseptic treatment. The lecture occupied several hours in its delivery, and was a most masterly exposition of Professor Lister's views on a subject which is to the Profession of vital importance, and ought to be speedily placed in the legitimate position it should occupy in our index of curative auxiliaries.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 30, 1871.

### THE ORIGIN OF LIFE.

At the present moment when the germ theory and disinfection are occupying so much attention, we may recur once more to the proceedings of the Association for the Advancement of Science, for the purpose of noting one or two of the papers brought forward, and the remarks to which they gave rise. They were not reported in our account of the proceedings, because we intended to refer to them in this place.

A very able member of our profession, Dr. Charlton Bastian, F.R.S., described some new experiments, the results of which have led him to conclude that living matter might arise *de novo*, and that this living matter might go on to the development of certain common organic forms, just as surely as any speck of crystalline matter in a fluid might take on and assume certain definite characters which belonged to the saline substance in its crystalline condition. His experiments showed that living organisms had been found in fluids that had been exposed to a temperature higher than was sufficient to destroy germs. Another enquirer, Dr. John Dougal, treated of the germ theory in a paper "On the Relative Powers of various Substances in Preventing the Generation of Animalcules, or the Development of their Germs, with Special Reference to the Germ Theory of Putrefaction.

Another set of experiments was described by Dr. Ferrier. These were made by him in conjunction with Dr. Burdon-Sanderson, with a view to discover the circumstances which determine the existence of bacteria in the liquids and tissues of the body. The paper had reference to certain results obtained in the course of an investigation into the ultimate nature of contagion. It was shown that in the test-liquids which they used for the detection of organisms in contagious fluids, no spontaneous evolution of organisms takes place. The occurrence of organisms in these liquids was in proportion to the degree of external contamination. Fungi are the chief form

which is derived from the air. The occurrence of bacteria is, however, due to water. It was shown that every kind of water, with the exception of freshly distilled water, teems with invisible germs of bacteria. These cannot be detected by the microscope, or by the electric beam in the manner adopted by Professor Tyndall. The purest-looking ice-water was found to contain as many germs as others which had not the same apparent purity. Different varieties of water possess the zymotic power, as they term it, in different degrees. The water supplied by the London water companies was examined, and different degrees of bacteria impurity were found to exist. They further showed that the animal liquids and tissues do not in the normal state contain the germs of bacteria, and that the occurrence of these, and consequent putrefaction, was due to contact with surfaces of ordinary water. Bacteria seemed to be the pioneers, if not the producers, of putrefaction. It was found that meat, milk, wine, &c., do not putrefy if they are kept from contamination with water, or any surface which has not been super-heated, or rendered innocuous by some anti-zymotic which is fatal to the life of bacteria. The experiments further showed that there is no developmental connexion between bacteria and torula; consequently Hallier's theories fall to the ground.

A discussion naturally took place on those papers, and will continue in various other directions. Two of the speakers looked upon the experiments as inconclusive, and many will agree with them. Thus Dr. M'Kendrick observed that some experiments he had himself made did not warrant him in forming a conclusion as to Dr. Bastian's experiments, he thought that the germs or ova of living creatures must always be more delicate and likely to be destroyed than the creatures themselves. Dr. Lankester who also considered the question to be still open, said Dr. Bastian wished them to believe that his experiments had proved spontaneous generation; but there were other and more interesting spheres of observation, and it would be found that it is in the slimy deposits in the depths of the sea that we must look for the solution of the difficulty. The question he said was not a religious one. Philosophers were quite justified in looking for the truth, and no theory or view should be suppressed that might at last turn out to be true.

### THE UNIVERSITY COLLEGE HOSPITAL BATHS.

It has been written of a Profound Philosopher, that a query having been put to him as to the means by which he acquired wisdom, laconically replied in words to the effect that, on all subjects of which he was not truly master, and on which he desired to be enlightened—and he was always on the look out for such subjects—he placed in his coat tail pockets, for the time, his natural modesty, and boldly asked for information of the most likely person to render it.

Had that Profound Philosopher flourished in our time, and in our busy metropolis, we question if his patience, and if his thirst for information would be able by any possibility to bear him up against the strain exercised upon it by the fresh and fast flowing changes he should hourly witness. For the world of London is a world of change undoubtedly, a great drama *en tableau*—ever on the shift. To-day we plan, construct, and embellish, tomorrow we go in for open spaces, ventilation, levelling, tide bounding, tramways.

Occasionally we handle in a most unbecoming manner, too, the creations of our forefathers, and knock upon the head a spire, or obliterate and gloss over an historical land-

mark, and raise in place of it a temple to the glory of steam at high pressure, by whose awe-striking unsightliness, its promoters hope to raise a higher wind.

And what wild and extravagant notions on "what is being doing?" are openly expressed by members of a wondering crowd, as they stand to witness the progress of any great undertaking.

A short time ago there was a crowd in front of the University College Hospital; as we passed its margin, we enquired if an accident had occurred, and why were the people gazing into its basement? Whereupon a bystander informed us in confidence, that no accident had been brought in, but that there was in course of construction, an underground passage, from the hospital to the Gower street station of the Metropolitan Railway, by which passage cases of accident from collision on the lines, could be conveyed to hospital without causing commotion from without, and the progress of that work they stood and viewed.

Now, had we been mindful in our humble way of the example set us by the Profound Philosopher alluded to, we might have at once emerged from the moody and chaotic state of despondency, the words we heard forced upon us. Had we consulted an authority at the University College Hospital—and there are to be met there occasionally some singularly gifted authorities—we might have continued our ambulation with mental composure, and subsequently have taken on our nightly slumbers to dream pleasantly of Dr. Tilbury Fox and his truly philanthropic doings, instead of passing a restless night of it, painting shadow pictures of orphans, slip-shod and out at elbows, widow's wooden legs, and—actions-at-law.

The members of the profession, generally speaking, are aware that Dr. Tilbury Fox occupies the Chair of Cutaneous Diseases at the University College Hospital, that for many years past he has made the Pathology and Treatment of Skin Disease his especial study, and that he has written trite practical and progressive works on the subject. Theories may do very well for the student and for the lecturer, but be they ever so trite and so progressive unless backed up by results attained and exhibited through practical experience, they fall very far short, indeed, of either their ideal or their true value. Thus it was at the University College Hospital, and thus it is (but now a start has been made, the example will be followed) at the majority of our general hospitals. There was a total absence of suitable baths, by which the complete eradication of many cutaneous affections could be accomplished, and nervous affections, rheumatism and many kindred disorders alleviated or cured. So professors might exhibit to their classes their patients and point out true remedies for the alleviation of their complaints, but not *prescribe* those remedies.

Dr. Tilbury Fox at length took upon his shoulders the full responsibility of improving this state of things, provided the governing body of the University College Hospital placed at his service some frowsy lumber cellars, and—their confidence. The proposal was accepted, but on the understanding that the ordinary resources of the establishment were not to be employed in the projected improvements. Preliminaries being thus satisfactorily arranged, Dr. Tilbury Fox next availed himself of the invaluable assistance of that Paxton of Hospital Construction Architects, Mr. Michael P. Manning, and ere much time elapsed the *employés* of Messrs. Jeakes and Co. were in full swing. And the result of all this is the erection—where on a time frowsy lumber rotted, and cockroaches frisked—of the most complete lavatory and fumigating *depôt* the country possesses, and of which the friends of any public institution may be justly proud.

Here let us state that the labour of love undertaken by Dr. Tilbury Fox was labour indeed. Bricks and mortar, metals and cunning hands to manipulate them are all expensive adjuncts, and to collect the one thousand five hundred pounds or thereabouts expended in this priceless undertaking, must have cost its promoter

some anxiety. To him the governors, and sincere well wishers of the University College Hospital owe *something more* than their heartfelt thanks. Of him and of the result of his labours in their behoof, the profession and the afflicted poor will speak in a kindly way long after his time.

And now let us turn to the annexed plan of the work accomplished. In the first place it shows us that the University College Hospital baths consist of two portions. They are excellently lighted from their summits, and ventilated in such a manner as to enable the bath attendants to regulate the supply of pure air, and the expulsion of the vitiated. The drainage of water, waste, steam, &c. from these departments, has a special trapped outlet into the sewer—which runs several feet external to the hospital—and it is not in any way connected with, nor influenced by the ordinary drainage of it.

As we pass to the vicinity of these baths we tread the summit of a double-winged and massively constructed, yet very artistic-looking iron stairs; by the left wing we enter the department for the treatment of contagious skin complaints, fumigating chambers, &c., and by the right wing we enter the general bath hall. From the lobby—indicated in the plan—we approach this hall. It has attached to it a partitioned dressing platform, that shall be used in common by patients from the baths in the hall, and those also from the Russian or Vapour bath.

The general bath hall is thirty feet by twenty-three feet. E shows the arrangement of the douches, trough shaped eight feet square, eighteen inches deep without overflow, and approached by two steps from the sides, and two steps of descent. D is a platform on which the operator stands, and from this platform he is able to work the levers that control the supplies to the douches, wave, solid column, and several shower baths. Such also is the arrangement for the working of the needle bath, situated at the opposite side of this department. A view of the action of this bath will fully repay a visit to the hospital.

The baths being porcelain, acid and alkaline, as well as water baths, may be given in them. They are intended for the treatment of nervous affections, rheumatism, neuralgia, chronic urticaria, &c. C is an uterine douche, fixed on a novel principle, and capable of exercising, if necessary, a tremendous amount of hydraulic force on the parts under treatment. The Russian bath is ten feet by twelve feet, and heated by radiation.

The means adopted for ventilating this room have been carefully attended to, plenty of fresh and good air is supplied. By means of an open grating each side the window, leading to two channels that incline downwards, and meet near the window frame; from thence a passage runs to the bottom of the floor, then along the side of the room to the left and the right, and round the side. There are inlets in each of the two sides of the room, that in which the window is placed and that along the air-channel for the egress of fresh air, and the amount admitted is regulated by a valve. Egress of air takes place at the top of the room and on the right-hand side, into the chimney, through a valved grating, so the current of air is quite under control. The furnace is placed in one corner, and the flue, made of fire-tiles, runs round three of its sides, above the fresh-air flue on the two sides where it exits, and is then returned thrice across the room, beneath the fire-tiled floor which forms the upper covering of the flue, until it arrives at the point whence it started, it is then carried up beside the stove into a chimney. The air admitted into the room is gently warmed by passing under the flue in part of its course, and the room is heated by radiation from the fire-tiles of the flue from the floor and sides, and without oxidation taking place, which is the case when iron surfaces are employed. This room is also arranged for vapour bath purposes. A steam jet is placed so that, when required, it can be readily to hand. The cases appropriate for treatment in this room, are Bright's disease, acute rheumatism, amongst general diseases; and

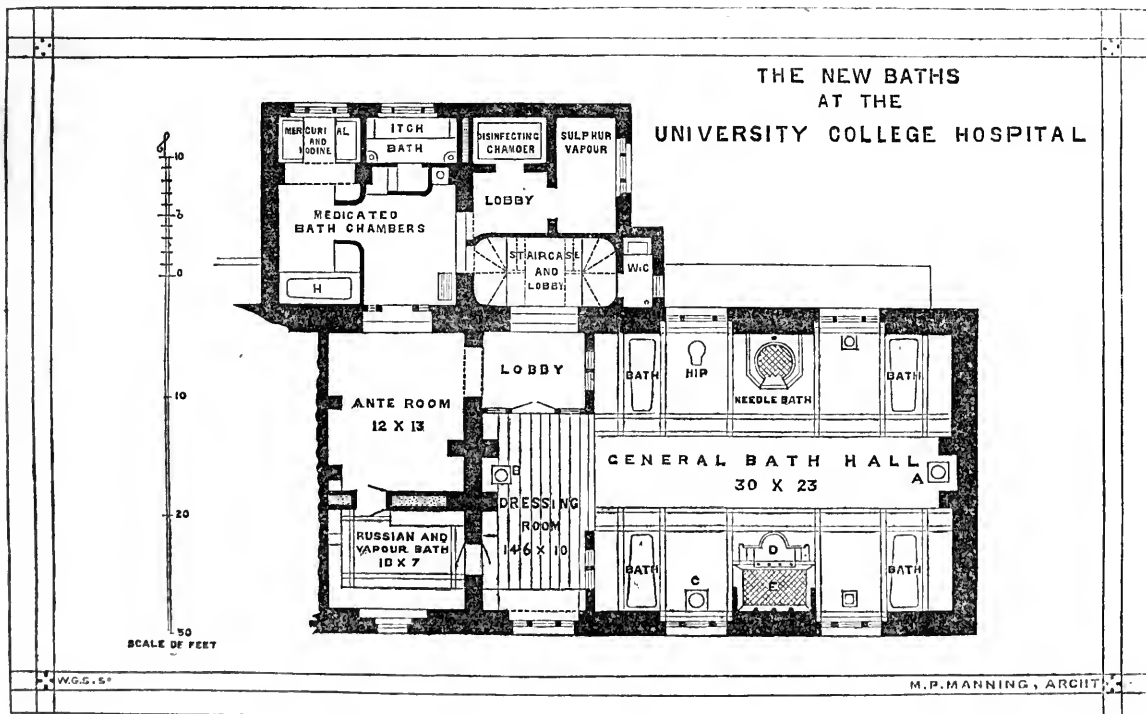

lichen, true prurigo, pruritus, and some other affections, amongst the cutaneous.

The bath hall is heated by two steam coils, one at either end, and the floor is tiled, and the walls cemented. The other section of the baths, devoted to the treatment of contagious skin complaints, and to certain forms of syphilitic disease, is reached by a separate entrance distinct from that leading to the general bath hall, and from the main staircase on the left-hand side. On descending we reach a dressing-room, to which are attached two recesses, that on the extreme left as indicated in the plan, contains the mercurial vapour baths. Here a very perfect arrangement has been adopted to volatilise the mercury employed, and at the same time dilute it with aqueous vapour, ere it reaches the patient. Gas jets are permitted to play on and to heat strong cast iron plates fixed in such a manner as to receive the heat without permitting effluvia to enter the baths. On these plates rest iron boxes, which shall contain the substance to be volatilised by means of the heat of the plates, and as volatilisation takes place, a lever is turned and steam is admitted, and mixes with the denser material, and both ascend through the perforated wood-work—on which the patient is placed—and encompass him as with a mantle of mist. The other recess contains the itch bath. The bath for giving sulphuret of potassium, which remedy is regarded by Dr. Tilbury Fox as most successful in certain cases of chronic diseases of the skin in a scaly condition, and for many cases of lichen urticatus, prurigo, &c., is opposite the mercurial baths. The itch bath is a walled-off recess, and so built as to receive a large amount of water without overflowing. There is a

large marble slab fixed here, where patients can sit and apply the parasiticide, which they may place on a shelf close by. Basins with supplies of hot and cold water are near to hand, and above them on either side is a rose, from whence a stream of water can be made to fall so as to thoroughly rinse their bodies. Dr. Fox proposes to cure itch cases at a sitting of half an hour. From this room we enter the disinfecting chamber (which can be heated red-hot, and has a special flue, running to the top of the building), here the apparel of the itch patients will be hung up to be disinfected, whilst they are taking appropriate baths. The ventilating of this room can be so regulated as to force at high pressure into the main flue, the charred deposits from the patient's apparel. The room on the extreme right is the "sulphur room," it has double doors, here vapour sulphur baths will be given. In the main room are boxes for macerating and steaming arms and legs, as in cases of psoriasis.

There is no woodwork save the doors, and little paint throughout; the walls are cemented, so as to be effectually cleansed by washing. The floor is tiled, and the mercurial boxes are supplied with steam.

The disinfecting chamber will be of great value in disinfecting the clothes of patients suffering from prurigo senilis (properly phtheiriasis or morbus pedicularis). At the present time the treatment consists of applications of parasitides to the bodies of the affected, whilst the real cause of the mischief, the pediculi, dwell in folds of the linen; and what is needed in these cases is the destruction of the vermin in the clothes, and a thorough cleansing with soap and water of the skin of the sufferer.

## Notes on Current Topics.

### The Pollution of Rivers by Manufactures.

THE Commission appointed to make inquiries into the pollution of rivers caused by any particular manufacture, have published the result of their investigations.

Around the localities of Bradford and Leeds, of Halifax, Huddersfield, and Wakefield, are collected many gigantic establishments. Here the materials used annually are quoted in detail, representing enormous quantities of log-wood and similar dyewares, chloride of lime, ammonia, and oil of vitriol, Gallipoli oil, soap, alkali, and coal. In consequence of such establishments, the beds of the rivers

have been silted up, and where formerly trout were very plentiful, now no living thing can exist except rats.

In the West of England we learn that the character of the pollution due to the manufacture of short wool can be nowhere better studied than on the small streams uniting below Stroud, in Gloucestershire. Upwards of 25,000 pieces of cloth are made in this district annually, and the greater part of this large quantity is black and blue cloth.

The Commissioners recommend that the casting of any solid matters, of whatever kind, into rivers and running waters be absolutely prohibited, and that immediately; that the discharge of any polluting liquids, which transgress certain limits assigned, shall be prohibited, but a reasonable time be allowed for the execution of the necessary works for purification. They recommend also that all rivers and streams in England be placed under the superintendence of central boards, whose duty it will be to exercise a surveillance over both the quality and quantity of the water supply of towns, and to investigate all schemes connected with river conservancy, and to refer such matters for the consideration of one of Her Majesty's principal Secretaries of State.

#### Precautions against Cholera in London.

THE Medical Inspector of the Privy Council, who has been charged with the supervision of the precautions against the importation of cholera into the Thames has arranged with the Board of Customs, the Trinity House, and the Thames Conservancy, as also with the authorities at Gravesend, and with the health authorities of all the riverside districts below London bridge, in order to obtain their co-operation in carrying out a complete and uniform system. At Gravesend ships are boarded by the Custom-house officers, and where the presence of cholera among the crew would be detected. It would be unfair to make the expense of providing for such patients and of disinfecting a charge upon Gravesend, and one of the main objects has been to bring about a consent that the cost should be equally divided. Pending the result of the efforts thus made to insure combined action, Dr. Buchanan has held communication with all the medical officers of health, and with other health authorities in certain districts, in order to secure that they may be prepared for the duties which may devolve upon them, and fully acquainted with the steps which they will be called upon to take if cholera should appear.

#### The Management of the Orthopædic Hospital.

##### Committeemen "Letting well alone."

An inquest was held last week on the body of Henry C. Bard, æt. five years, who died in the Orthopædic hospital from an attack of diphtheria. It was alleged by the medical officers that the death of the child had been accelerated by the defective sanitary condition of the hospital. The housekeeper and matron of the hospital said there had been five children who had died from diphtheria in it since the beginning of April.

Dr. Bourne, resident house surgeon to the hospital, considered the attack of diphtheria from which the deceased had died was accelerated, if not produced, by the defective sanitary condition of the hospital. Upon entering on his duties, four weeks ago, he found the general and

sanitary arrangements as bad as they could possibly be, both with regard to the diet, the cooking, the cleanliness, and the knowledge and the attention of the matrons and nurses. There was no order or regularity. The patients were left unwashed for days together, and the atmosphere of the wards was damp and moist, owing to the washing and scrubbing taking place at all hours of the day, instead of early in the morning. On the 3rd of August, before the death of the deceased, he had sent in a written report to the committee, describing the condition of the hospital. He attended before the committee, and read that report himself. While before the committee he also made a verbal communication as to the gross mismanagement he had witnessed in the wards. He then left the committee room, and in five minutes afterwards he received a written note from the committee requesting him to send in his resignation, and on the alleged ground that he could not agree with the other officers of the hospital. He fully believed that the deaths from diphtheria which had taken place in the hospital would not have occurred under proper sanitary arrangements and good nursing.

The Chairman of the committee cross-examined Dr. Bourne, but did not shake his evidence in any material point.

Dr. Tamplin had heard the evidence of Dr. Bourne, and generally agreed with all he had stated. He had frequently called the attention of the committee to the general want of care and cleanliness on the part of the nurses, and the dirty state of the patients.

Dr. Adams had heard the evidence of Dr. Bourne, and agreed in the main with all that he had stated.

The jury, after some deliberation, returned the following verdict:—"That the deceased died from diphtheria, but we recommend the committee to adopt and act upon the suggestions of their medical officers, especially with respect to the appointment of a regularly trained nurse."

#### The Coming Cholera.

At the Paris Academy of Medicine recently, the following statistical statement as to the mortality in Russia from the epidemic of cholera which now threatens Great Britain was laid before the Academy.

From the 29th of August, 1870, to the 31st of July, 1871—

|            | Males. | Females. | Total. |
|------------|--------|----------|--------|
| Cases ...  | 4,568  | 2,249    | 6,817  |
| Cures ...  | 2,346  | 1,196    | 3,542  |
| Deaths ... | 1,938  | 859      | 2,797  |

During the debate M. Delpeche remarked that an epidemic which had lasted more than a year could not be considered as ephemeral or vernal. But, on the other hand, it could not be considered very alarming when, during the lapse of that period, it only caused 2,797 deaths—that is less than 10 *per diem* on an average.

The female cases were barely a third of those occurring in males either in respect of frequency or mortality.

#### Vital Statistics.

*Marriages.*—There were 6,082 marriages registered in Ireland during the fourth quarter of 1870, or 449 per cent. of the estimated population. Of this number only 1 marriage in every 279 or 359 per cent. were Roman Catholics; and 1 in every 134, or 747 per cent were Pro-

testant, The average in the corresponding quarter of the previous five years was 6,383.

*Births.*—The births during the quarter amounted to 41,637—1 in every 32·4, or 3·08 per cent. of the population. The average during the corresponding quarter of the previous five years was 38,847.

*Deaths.*—There were 26,510 deaths—1 in 51·0, or 1·96 per cent. of the population. The average number was 27,632.

It is but too apparent from the foregoing figures that the registration of births and deaths is still very imperfect, the annual ratio of births to the estimated population in England being about 1 in 29 or 30, and of deaths, 1 in 44 or 45; whilst in Ireland, according to the present return, the ratios are—for births, 1 in 32·4; and for deaths, 1 in 51. The registration of marriages under the provisions of the 26 and 27 Vic. cap. 90, it is greatly to be regretted, is still more unsatisfactory.

*Estimated Increase of the Population.*—The number ended 31st March last being 41,637, an increase of 3,772 would appear to have taken place in the population of Ireland during that period.

The average number receiving in-door relief during the quarter was 52,096, against 55,867 for the corresponding period of 1870.

The average receiving out-door relief was 24,748 against 21,727 during 1870.

*Health of the People.*—The state of the public health during the past quarter has, with some exceptions, been satisfactory. The harsh easterly winds proved very fatal to the aged and infirm, and the principal mortality was due to pulmonary affections. Small-pox, which prevailed and unhappily still prevails to an alarming extent in England, made its appearance in about twenty districts of the country. In almost all the cases the infection could be traced to English or Scotch sources. In the month of January an English recruit was admitted into the General Military Hospital, Phoenix Park, labouring under small-pox. A female servant (with bad marks of vaccination) employed in the hospital was attacked with the disease, which assumed a confluent. She was removed to the Mater Misericordiæ Hospital, and ultimately recovered. The number of small-pox cases treated in the Mater Misericordiæ Hospital up to the 24th of March amounted to 15, of these 7 were confluent, the others modified; two of the Sisters of Mercy, four students, a ward maid, and the cook contracted the disease, all recovered.

The Registrars generally report most favourably of the working of the Compulsory Vaccination Act, and the beneficial results are manifest. The poorer classes who formerly entertained the strongest prejudices against vaccination now are most anxious to have the operation performed on their children. Nay, more, the number of adults who have been vaccinated and re-vaccinated within the last three months is very considerable.

Scarlet fever was not so prevalent as usual; in some quarters, however, it proved very fatal.

Some of the Registrars refer to the presence of fever, croup, measles, and whooping cough in their districts.

While some of the Registrars report favourably as to the improvements in the sanitary condition of their districts, many more refer to the prevalence of disease as induced by the total want of all sanitary administration, and the filthy habits of the people.

### Prevention of Drunkenness in France.

THE French National Assembly had under consideration on the 31st of July a Bill to add to the penal code certain provisions for the suppression of drunkenness.

The proposition was to punish by a fine of one to five francs those found drunk in the streets, and by a fine with three days' imprisonment those public house keepers who admit persons in a state of drunkenness, or young persons under sixteen years of age unaccompanied by their parents.

### Conjoint Extra- and Intra-Uterine Gestation; Cæsarean Section; Death of the Mother; both Children saved.

THE New Orleans *Journal of Medicine* publishes an account of an interesting case which occurred in the practice of Dr. E. P. Sale, of Aberdeen, Miss. It has been condensed and copied by several of our American contemporaries:—

The case was that of a Negress, in which Dr. Moore of the same place having diagnosed ovarian pregnancy (the woman was unmarried, and denied having had intercourse with man) he was called in consultation, and confirming the diagnosis, and further agreeing that the woman's condition was such that death must soon take place if nothing was done, ovariectomy was decided on as affording the only hope of saving either the mother or child. The necessary arrangements having been made, the operation was accordingly performed on the 3rd of March, 1870, and a living child, with the placenta, extracted, when, to their astonishment, the uterus (previously concealed by the ovarian pregnancy, and the os giving no indications of the fact) was found to be impregnated. After a hasty consultation as to whether to suspend the operation and endeavour to deliver the child *per vias naturales* or resort to hysterotomy, the latter was decided on and performed, and another living child and the placenta extracted. All clots were removed, and the wound closed and dressed with a solution of carbolic acid, and the usual treatment in such cases resorted to, but the woman died on March 7th, the fourth day after the operation, as was supposed of septicæmia. No *post-mortem* was allowed. At the time of writing the report, April 15th, both children were doing well.

### Chloride of Ammonium a Specific in Hepatitis and Hepatic Abscess.

ACCORDING to a paper by Dr. William Stewart in the *Burma Press* and in the *Madras Monthly Journal of Medical Science*, chloride of ammonium is a specific in certain hepatic diseases common in India. He says:—

Since the 1st of September, 1869, from which time the systematic treatment of hepatitis by chloride of ammonium first commenced (a period of nine months), thirty-one cases of the disease have been treated, either by myself or the assistant-surgeons of the battalion; and of these, six were undoubted cases of abscess of the liver, presenting the physical signs, the general symptoms, and the well-marked hectic fever, diagnostic of the disease under such circumstances. In four of the cases, the hectic fever was severe; in one especially so, and accompanied with excessive wasting of the tissues, and extreme prostration of the vital powers—patient exhaling the cadaveric odour, at

times observed in low and exhausting disease with typhoid symptoms.

Hepatitis is a disease of this station, and has been the occasion of much mortality here, as elsewhere. From a statement, kindly furnished by Dr. Shelton, Principal Medical Officer, British Medical Service, I find that in the headquarters of the 24th Regiment, Rangoon, and Detachment, Port Blair, out of a total strength of 795, there were, during the year 1868, thirty-two admissions and five deaths from hepatitis. "The *post-mortem* in each instance shows the cause of death to have been hepatic abscess."

During the same period (1868) in the 21st Fusileers, at Secunderabad, out of an average strength of 868, there were eighty-six admissions and six deaths from the same cause. The disease was treated on the usual expectant plan, and with a result not very satisfactory. Compare these figures with those which follow, and see how different is the result obtained under the treatment by chloride of ammonium :

Since September 1, 1869, to May 31, 1870 (a period of nine months), there have been thirty-one admissions from hepatitis at this station, out of an average strength of 608 ; of these, six were undoubted cases of abscess of the liver, and in several abscess was strongly suspected. All of the above were successfully treated without a single death. It is also remarkable that, since the arrival of the battalion at this station at the end of December, 1868, up to May 31, 1870, embracing a period of seventeen months, there have been fifty-eight admissions from hepatitis, and but one death, the fatal termination in this instance furnishing negative proof corroborative of the testimony already adduced of the very great success of the chloride of ammonium treatment, for it is to be observed that the patient died at a period antecedent to the introduction of that practice, that dysentery of a very severe type supervened, uncontrolled by any of the remedies employed, and that the autopsy revealed the existence of abscess, which occupied almost the entire liver, the structure of which was reduced to a mere shell. The large intestine was ulcerated throughout its entire extent, and in places gangrenous.

In not one of the cases treated by chloride of ammonium was there the slightest tendency to dysentery observed.

According to the Army Medical Department Report for 1867, out of a total strength of 56,896 European troops in India, there were, during the year, 3,078 admissions from hepatitis, and 157 deaths. During the same period 368 were invalided on account of the disease, and 96 were discharged the service at Netley.

Careful nursing is necessary, as is also absolute rest in the recumbent posture, since relapses may occur from so slight a cause as an attempt on the part of the patient to turn in bed. In a further paper on chronic hepatic abscess he asserts that the remedy is equally efficacious. "In short," he says, "I have found it valuable in hepatic affections of whatever form, whether depending on organic disease, or functional derangement. I have also found chronic dysentery, associated with chronic disease of the liver, yield to a few twenty-grain doses of the chloride of ammonium, after ipecacuanha and other remedies had failed ; and I have before me notes of the case of a young officer, similarly affected, whose dysentery was checked after a few doses of eight grains each. In such cases from five to twenty grains may be given, dissolved in tw

ounces of infusion of cascarilla, twice or thrice daily, according to circumstances ; and, to cover the saltish taste of the medicine, a little ext. glycyrrhizæ (say grs. v) may be added to each dose. In passive congestion of the liver from cardiac disease, I have found a few doses (grs. xx.) of the medicine effect a remarkable reduction of the enlarged viscus, and afford great relief to all the symptoms ; in fact, the specific action on the liver is manifested in almost all the diseases to which that organ is liable."

#### Quinine, Quinodine, and Cinchonine.

DR. J. B. HAMILTON (*Indian Medical Gazette*, March 1, 1871) gives the result obtained from the use of quinine, quinodine, and cinchonine, as prophylactics against malarial fevers. He divided the troops under his care into three parts, each part to receive but one of these alkaloids. Every man took three grains of quinine, quinodine, or cinchonine, as the case might be, and such cases of malarial fever as were developed were treated with the same alkaloid as he had been taking as a prophylactic. After giving the results of the trial, Dr. Hamilton concludes :—

"From the above facts it would appear that quinodine ranks highest as a prophylactic, as the men treated with it show only 7·7 per cent. of admissions.

Quinine ranks next, giving 8·7 per cent., and cinchonine undoubtedly last, showing 19·4 per cent. of admissions.

It must also be borne in mind that these men were all under exactly the same conditions, as to residence, food, clothing, exposure, night duty—in fact, three bodies of men more evenly situated in every way could not be found.

Now, as regards the immediate action of the drugs, an undoubtedly tonic effect was produced by all.

The action of quinine is so well understood, that it would be superfluous to touch on it.

Quinodine seems to act nearly in every way in a similar manner to quinine, and the cases treated with it in the ordinary way yielded as readily to the equivalent doses as they would have done if treated with quinine.

Some complaints were made of diarrhœa having been caused by it, but on investigating them I came to the conclusion that they were all due to other causes, chiefly climatic, and that, on the contrary, the number of admissions from diarrhœa was very low, being only three for the months the drug was being given in the whole battery.

Cinchonine did not give such favourable results ; no doubt it has a certain amount of tonic, prophylactic, and anti-periodic power, but it was less efficacious and certain in its effects, requiring larger doses than either of the others ; the paroxysms of fever returned oftener, and in many cases I had to omit it and finish the cure with ordinary doses of quinine.

In conclusion, I beg to express my opinion, founded on the experience of five rainy seasons—two at Jubbulpore, two at Hazareebagh, and one at Allahabad—of the great benefit accruing from the use of quinine (or its allied drugs) issued as a prophylactic during the months of August, September, October, and of a late wet season, November ; the cases of ague are fewer, of a milder type, yield more readily to treatment, and seldom assume the remittent form.

### Structure of the Glands of the Stomach.

IN Schultze's *Archiv. für Micros. Anatom.*, Bd. vi., there is an account of Professor Heidenhain's investigations on the structure of the gastric and peptic glands. The mucous membrane of the stomach of dogs was hardened in alcohol, then stained with carmine or aniline blue, and examined with moderate microscopic powers. The glands are arranged singly like palisades, or in groups like the fingers of a glove, in close proximity to one another, and the orifice, neck and body in each can be distinguished. The orifice in the grouped glands resembles the hard part of the glove, several glands opening into it, just as the fingers of the glove open into the wider hand part. This is lined by columnar epithelium. The neck or narrower portion of each tube is lined by roundish coloured cells. The body is lined by two kinds of cells, one external or marginal, round, and coloured, the other small, internal, and uncoloured, though their nuclei sometimes become tinted. The former Professor Heidenhain calls investing-cells (*belegzellen*), the smaller uncoloured ones he names chief-cells (*hauptzellen*). The former probably represent the peptic cells of writers. The lumen of the glands is occupied by granular dark material. He describes with full details the action of the various reagents upon the two above-mentioned forms of cells. He then gives the results of his researches on the glands during digestion. They increase in size; the chief cells become swollen, and their contents are finely granular, showing that they have absorbed more than they have secreted. The investing cells are less altered. No division or multiplication of cells was observed.

### Social Science Congress.

THE special questions for discussion at the Leeds Congress of the Social Science Association to be held from the 4th to the 11th of October, under the presidency of the Right Hon. Sir John Pakington, Bart., M.P., have been finally arranged by the general and local committees of the several departments, as under:—

*Jurisprudence.*—W. Vernon Harcourt, Esq., Q.C., M.P., president.—1. What steps ought to be taken to establish a better system of legal education? 2. What is the best constitution of local courts, and what should be their jurisdiction? 3. What alterations are expedient in the laws relating to the devolution and transfer of land?

*Repression of Crime.*—Lord Teignmouth, chairman.—1. How far ought the cellular system of imprisonment to be adopted; and how far does it necessarily interfere with productive labour? 2. By what principle ought the amount of punishment, other than capital, to be regulated? 3. By what measures may the trading in stolen property, whether by purchasing it or receiving it in pledge, be most effectually prevented?

*Education.*—Edward Baines, Esq., M.P., president.—1. What are the special requirements for the improvement of the education of girls? 2. How may the education of neglected children be best provided for? The question to be considered under the divisions:—(a.) Industrial schools and their relation to the school boards. (b.) In what form, if any, may compulsion be best applied? 3. What are the advantages and disadvantages of large as compared with small schools?

*Health.*—George Godwin, Esq., F.R.S., president.—1. What are the best and most economical methods of

removing and utilising the sewage of large towns? 2. What are the best means of securing the sanitary improvement of human habitations? 3. What are the best means of promoting the health of operatives in factories and workshops?

*Economy and Trade.*—William Newmarch, F.R.S., president.—1. What amendments are needed in the existing laws for the licensing of houses for the sale of intoxicating liquors? 2. What principles ought to regulate the assessment and administration of local taxation? 3. Is it desirable that the state or municipality should assist in providing improved dwellings for the lower classes; and, if so, to what extent, and in what way?

Each of these questions will form one day's labour to discuss, and two days will be set apart for the reading and discussion of voluntary papers on other subjects not specified above within the range of the departments.

### Medical Officer of Health for Islington.

THE resignation of Dr. Ballard will, no doubt, bring several candidates into the field for the Medical Officership of Health. Among those already announced we observe the name of Dr. Meymott Tidy—a gentleman whose high attainments in those departments of science most concerned, and familiarity with the duties of the office obtained under Dr. Letheby in the City of London, are the best assurance that in electing him Islington would secure a first-class man.

### New Source for Benzoic Acid.

THE urine of horses and cattle is utilised in Northern Prussia for the manufacture of benzoic acid. One house at Königsberg supplies the market from this source. The establishment makes 7,700 lbs. of benzoic acid annually, for which 3,850,000 lbs. of urine are required, not to speak of shiploads of fuel to evaporate it. Benzoic acid is now chiefly used in the manufacture of a red colour for woollen goods, and is also highly prized in making certain kinds of perfumery.

### Death of the Double Baby—One Head Out-lives the Other.

THERE was recently born in Boston a most remarkable child. It presented the phenomenon of two heads, four arms, and two legs, and all upon a single body. The girl for such was its sex—died recently. The first half or head breathed its last at five, and the second shortly after eight o'clock. The child had enjoyed excellent health from her birth, nine months ago, until within two weeks, at which time one half exhibited signs of illness. It recovered, but a few days since, the other—or the other half—was taken sick, and died. Upon one end of the body reposed the head of the dead infant; upon the other that of the live one, with its eyes still bright and curious, and its lungs in full breathing order.

### Public Vaccination.

SOME excellent instructions have just been issued to public vaccinators by order of the Privy Council. In the first place, vaccinators are told to refrain from vaccinating, except in cases of urgency, any but those in good health, or such as have been recently exposed to the infection of measles, or scarlatina, or erisipelas. Four distinct punc-

tures are recommended. Directions are given to vaccinate from arm to arm where possible. Vaccinators are especially told to prevent any admixture of blood with the lymph that is taken from a vaccine vesicle. In the collection of lymph the vaccinators are told to seek first in the subjects of healthy parentage and children whose families are known to them especially, and who have elder brothers and sisters of undoubted healthiness, and in addition never to take lymph from cases of re-vaccination.

### The Government and the Profession.

We have on two occasions called attention to the unjust neglect, by the Government, of the two distinguished Army Surgeons, who were *officially* in Paris during the siege—a neglect the more culpable as the French Government has recognised their services by a special decree, creating them officers of the Legion of Honour. The *Gazette*, however, does not yet record the promotion or other reward of either Surgeon-Major Wyatt or Deputy Inspector-General Gordon. Why? Is it to be understood that the Medical Profession alone is to be denied recognition, when other branches of the public service are praised and rewarded? We appeal to the public opinion of England against such a decision. It is an insult to Army Surgeons that will cost the country the services of many a high-minded man, who will be prevented from entering the army on finding that two men, who happen to belong to the Medical Profession, are treated worse than others simply because they are members of the Profession on which the health of armies depends.

We are glad to see that the subject is not likely to drop. The *Times*, the *Army and Navy Gazette*, the *Globe*, the *Standard*, and other journals have already referred to it; and, we hope, that our contemporaries generally will endorse our statement that, to insult the Profession w—only can only end in depriving the army of the best men. In our last issue we reported the renewed refusal of the Government to lay on the table of the Houses of Parliament the reports of these men. In the interests of military surgery those parts of their reports which relate to strictly professional matters ought to be published, and we hope they will appear in the next report of the Army Medical Department.

### The Plymouth Meeting.

ALTHOUGH a good number of people went to Plymouth they did not all put in an appearance at the reading of the papers. Some of the papers were, in fact, "taken as read," because there were no auditors.

In the face of this it may be well to consider whether the division into several sections is desirable.

THE Brighton poisoning case is not yet concluded, and strange as it is, we think it best to avoid comment at this stage.

WHY cannot sea-water be brought to London in pipes laid along the Brighton Railway? asks the *Builder*, which adds:—"It would certainly pay. The water could be supplied to houses. It could be sold in quantities at the works. Salt-baths could be established in connection with the works, and a salt-water lake similar to the lakes in our public parks would be a great attraction."

ANOTHER fasting girl turns up in the newspapers, on which the *Globe* expresses a hope that "London Doctors" will not spend a holiday in getting up another sensation.

DR. FREEMAN J. BUMSTEAD, the well known professor of venereal diseases in the New York College of Physicians and Surgeons, has retired from practice, and proposes to spend some years in retirement in Europe.

THE death of the champion oarsman has given rise to a suspicion of foul play, for which, so far as the evidence has been published, we can see no reason. Sudden death in such a struggle in a man who had had fits, is not so very astonishing.

THE *Bombay Gazette* hears it has been determined to separate the civil from the military branch of the medical service in India. Army surgeons will be called upon to choose which branch of their profession they will continue to serve in; and those who choose military service will be placed under Inspectors General of the Royal Army, while the civil surgeons will have a chief appointed by the Indian Government.

A NEW and rather alarming fact has been established during the occurrence of a thunderstorm in Paris on the 3rd of August. Two gasholders at a considerable distance from each other were exploded by a discharge of lightning. It has never been thought that electricity is capable of inflaming coal gas, and as every town has its magazine it is a very serious discovery that it is so.

M. De Fonville has ascertained that the electric fluid was conducted to the gasometer by a neighbouring house gutter.

THE Bombay Government, says the *Globe*, has at last taken into serious consideration the necessity of doing something to put an end to the scandal caused by the disgraceful want of suitable accommodation for insane patients in the Lunatic Asylum at Colaba. The wish of the Government is, if money can be found for the purpose, to build two new asylums, one in the Concan and the other in the Deccan; and it is also proposed to spend some 20,000 rupees in altering the present asylum so as at least to give the male and female patients separate apartments.

A RECENT number of the *Annalen der Chemie und Pharmacie* contains the result of an interesting investigation on Himalaya tea by Th. Zoeller. The results lead to the conclusion that Himalaya tea is quite equal to the best Chinese tea, but it must remain undecided whether the presence of theobromine is accidental, or constitutes a distinction; the results also bear out the experience of tea planters, that the youngest leaves of the tea plant give the best quality. In reference to the action of tea upon the human system, the author again points to the richness in potash, the importance of which in nutrition has been demonstrated by Kemmerich's experiments.

MR. W. G. M'IVOR, Superintendent of the Cinchona Plantations in British Sikkim, has published a lengthy report, of which *Nature* gives the following abstract:—"The plantations are situated in the Valley of Rungbee,

in the Himalayas, which seem admirably adapted for the growth of cinchona. The climate is very moist, being rarely free from rain. Nevertheless, the state of the plantations is reported as very unsatisfactory; the plants have nothing like the luxuriant foliage which characterises those grown in Southern India on the Neilgherries. They seem to thrive for three or four years at the most, and then become diseased." Mr. M'Ivor says that trees of equal height do not produce so much bark as in the South of India, being of more slender growth, and the bark being thinner.

## New Inventions.

### ARNOLD AND SON'S IMPROVED PORTABLE ENEMA (REGISTERED).

ONE of those simple improvements that, when once tried, excite surprise that they were not thought of before, has been made by Messrs. Arnold and Sons, in the elastic enema apparatus. We very strongly recommend this instrument, with the full conviction that it is sure to please all who try it.

This Enema consists of an India Rubber Bottle, which is specially prepared to stand any climate, and is fitted with a reversible pipe and mount, to which is arranged a cap so that a patient can with safety carry the fluid with them, and by simply taking off the cap and reversing the rectum pipe it is then ready for use. The numerous advantages of such an instrument will at once be seen, as there is no possibility of its getting out of repair, and the mounts are made of brass, carefully tinned on the inner side, and every part which comes in contact with the fluid, so as to prevent corrosion.

They are fitted in various ways, and answer equally well as an Enema or Vaginal Syringe. A smaller size is made for injecting the Urethra, so that the patient can readily, and without fear of breakage, carry with him the injection and syringe ready for immediate use.

## SPECIAL CORRESPONDENCE.

### THE RHINE AND PARIS IN 1871.

[LETTERS FROM DR. CHARLES R. DRYSDALE.]  
To the London Editor of the MEDICAL PRESS.

August 10, 1871.

SIR,—In former years you have favoured me by inserting letters as to the facts I have noticed during a summer holiday trip, and I hope that this year, too, you will be equally indulgent, and bear with me, when I narrate what I have seen in a fortnight's trip to Paris, *via* Belgium and the Rhine. Now that that surgical part of society, the soldiers, have left off operating on each other *for a time*, perhaps a little medical and hygienic discussion may not be out of place. Leaving London at the latter end of July, I visited one or two of the Belgian towns, and, in passing, would only notice that, in particular, the town of Ghent is in much need of medical officers of health, since industrialism seems to be the only thing thought of in that town of narrow dull streets, without any pavement, or indeed, any agreeable feature that I could discover, except, perhaps, the large convent (Béguinage) of nuns, who wait upon the patients of the general hospital, and who dwell together in a little colony of houses, each house being labelled, not with the name of the lady who occupies it, but with that of some favourite saint, masculine or feminine. About six hundred of these ladies live thus in a quarter of Bruges, I heard.

In Brussels there is much for the medical man to admire, in the upper town, which is clean, without smells and very healthy, but I am sure that the gentleman who spoke at the Belgian Medical Society recently, concerning the unhealthiness of Brussels was quite correct, since the lower part of the town is ill drained and smells very badly indeed, from the want of sufficient water I suppose to flush the drains. M. Croq I know has recently disputed this; but I trust to my olfactory organs in this matter, and think that, as cholera is impending, the drains of Brussels should be looked to at once. I forgot to mention that Ostend is a most admirably clean town, and I think much more hygienic than its rival Boulogne-sur-Mer, the latter, as you of course know well, being anything but odorous at low water. The sands at Ostend, too, "leave," as the French idiom has it, "nothing to be desired." You will, I doubt not, regret to hear, that there is some intention of raising the fares on the Belgian State Railway, although the present rates, which are most pleasantly low for the traveller—about one halfpenny a mile for long distances in the first class—have not entailed, it seems, any loss to the State exchequer. To all who consider how valuable a little change of air, scene, and associations occasionally is to the health of mind and body of everyone, this determination of the Belgian Lower House will be, I feel sure, disheartening, as many of us too had looked forward to cheap fares in England and France at no very distant date. The Belgians are most intelligent, industrious, and thriving, and wages seem to me to be almost as high in that country as in France or England, and very much higher, as will be seen, than in Rhenish Prussia. Before leaving Belgium, I would remark, that I was severely treated by a mosquito, whilst sleeping at an inn close to the field of Waterloo. How is it that we do not hear of these plagues in England, when they seem to exist (this summer at least) in Belgium and all up the Rhine? You, who have been much in Italy, can, perhaps, explain this. At Wiesbaden they existed in swarms.

On crossing the Prussian frontier, at Herbesthal, it at once became evident that one had entered a country lately at war. Everyone in the train had some story to tell of relatives killed or wounded in the late detestable affair, or in what a state of panic the women were at the commencement of it, expecting that, perchance, the then Emperor of the French, with his brutal African troops,

might pass that way. Let us hope that no other form of government in France will in future commit the gross inhumanity of employing Zouaves against civilised enemies. It seemed to me, that almost all the adult male population at Aix-la-Chapelle (a horribly unhygienic place, and a disgrace to Prussia for its drainage) had been, directly or indirectly, connected with the war, and many wounded soldiers were to be seen in all directions in that city, who, when unable to work, were solaced, I was told, with twelve thalers a month = 36s., (or not quite two pounds a month) for the loss of their future prospects by imperial Germany. Several persons who spoke of this complained of the smallness of the recompense, for such hardships and sufferings, but added, that the *adelleute* of Germany were too numerous to admit of the disabled soldier getting more. The true explanation probably is, that Germany as Bismarck has it, is a poor country—*i.e.*, that wages are usually very low, and hence, that soldiers are very cheap, about one-third of the price that they are in England.

Cologne has been long noted for being a filthy town. I need not, then, say that it is a wretched place yet. What are the municipalities about, when they allow such a wealthy town as Cologne to remain in such a disgraceful state in the year 1871? Tobacco and beer alone surely could not lull the mind into oblivion of the smells, filth, and narrow dull streets of that ancient town. There were, I heard, still about a hundred wounded men in the Cologne Hospital, but these too, were expected soon to leave. I did not notice many wounded men in the streets of Cologne, although there were many poor fellows limping about at Bonn. Bonn is a most agreeably situated town, and the neighbourhood, with its views of Ehrenbreitstein, as romantic as could be desired, but there are parts of Bonn which *much* require the sanitary engineer, and notably the Rhein Gasse, where Beethoven was born, and other narrow lanes leading to the Rhine. The city millionaires of Cologne use Bonn and Godesberg as a kind of Brighton or Richmond, to sleep at, and repair to Cologne only for business. Hence, I presume, the neglected state of the latter city. It will, of course, be objected to what I have now said, as to the state of Cologne, Bonn, and, for that matter, of Mayence, Coblenz, and most of the Rhenish cities, that it is difficult to cleanse such ancient towns. I admit it, but contend, that the universal education of our respected cousins, the Germans, should be able to do better than leave these cities in such a deplorably unhygienic condition.

A person with sufficient means must be hard to please, indeed, if not contented with the charming scenery of the most beautiful of all European rivers, and yet, he will feel himself not so contented, when he learns how badly the poorer classes of that magnificent country are fed and nourished. In my opinion Germany is *far* more over-peopled than either England, Belgium, or France. The wages at Coblenz, at Mayence, and elsewhere, are terribly low. The labourer in the field along the Rhine earns I hear daily only about one florin, or one shilling and eight pence, although he rises at early dawn, and works on until sundown. His food is most scanty and uninviting. Black rye-bread, spread over with sour white cheese, seems to be eaten twice or thrice a day. Meat rarely is eaten by these men and women, and butter is now an un-heard of luxury. It may be from this cause, that there is so much scrofula observable among the peasantry on the Rhine. Happening to visit one or two of the churches, such as that at Remagen, when pilgrims were resorting there, I was struck with the number of cases of extensive lupus of the nose and face, seen among the devotees.

At Coblenz there seems to me to be a great deal of goitre, as I remarked four cases of it in the streets. The country around seems most healthy, so, I presume, there are some magnesian wells in that city, which should be looked to. As the bran-new Emperor of Germany selects the neighbourhood of Coblenz, Ems, for his residence in summer, perhaps his court physicians at their leisure might see to the drains and water supply of Coblenz.

Here, as elsewhere, there had been many wounded soldiers, but all were convalescent and sent home. I suppose that the Editor of the *Practitioner* will feel pity for me, when I say, that I am sorry to see so much land as that between Coblenz and Mayence occupied in the culture of the vine; but so it is. Among the other blessings we sea-girt islanders enjoy, I reckon that of not being able to grow wine, because, although doubtless a large part of our population are much too fond of drink, there is also a very large section of our community to whom all alcoholic drinks are a luxury, and not as in Germany or France, almost a necessary of life. Thus, when I saw the half-fed working classes of Coblenz drinking Moselle wine habitually with their scanty meals, I could not keep thinking, that their scanty wages might have gone much further had not the Romans planted the vine on the banks of their noble rivers. You will not expect me, perhaps, to leave Germany without noticing the question of human Darwinism. Well, then, families seem to be very large throughout the Rhine district. Ten or twelve children are not uncommon in families there, and the landlord in one place had had eighteen children. Hence, the low wages, doubtless of that favoured land, and the continued stream of emigration towards London and the United States from all parts of the Rhine country. In Mayence, Coblenz, Worms, and Mannheim, there were everywhere agencies for emigrants to the States. Now, I hold, with Chalmers, that whenever any people are anxious to leave their native land in such great numbers, that country is terribly over-peopled in proportion to its capacity; and, we know too well in England, Ireland, and Scotland, how many superfluous hands we always have, who are thus like the poor Germans, thrust out of their native land by the thoughtless reproductive mîds of their parents. When Germany has gone through its war fever, and become well united, I humbly recommend its writers to study the customs of France on this head, where they will find a well-fed peasantry, with decent wages and comfort, in many of the provinces, such as Champagne, Lorraine, and others; where wages are *at least* double those of Rhenish Prussia, of course, on account of the paucity of births, a topic which so terrifies some of our respected brethren at home, as to render them quite stupid.

At Wiesbaden there were numbers of wounded soldiers and officers walking about, but, I am glad to say, not playing at that abominable gambling table, which is doomed and to be given up, either next year or the year after. It is sad to see the high play that goes on at the mournful *rouge et noir* tables, and the anxious dyspeptic look of some of the votaries. I am glad to hear that Prussia sets her face against such goings on, and that "*Messieurs, faites le jeu,*" will not be heard in any part of the Vaterland in a few years at furthest. Alcohol, tobacco, and gambling, seem to me to be the three most dangerous vices to which the race is at present a prey. Wiesbaden, in every respect, save that of its gambling propensities, is quite a delightful residence, and the heat of the springs there make the warm baths, doubtless, most agreeable and curative in rheumatic affections. The German bathers drink the water, to music, from six to eight in the morning, and these early habits are most invigorating to Londoners accustomed to late hours and late rising. As to the virtues of the waters, internally, I heard nothing very convincing, and rather suspect, that common salt is one of the chief ingredients. Talking of tobacco, I perceived, in a walk from Mannheim to Heidelberg, that a large quantity of that pernicious weed is farmed in the duchy of Baden, and I quite agree with my learned friend, Dr. Webster of London, that the German nation is seriously injured by the almost universal habit of smoking, which so strikes a stranger in that country.

It is all very fine to be able to fight well; but, surely, that is not the most important question now-a-days for civilised men and women. Social customs and simple hygienic life, I am sure, will, in the future, excite far more

interest than the power of destroying some neighbouring State, or of obeying the orders of some rigid disciplinarian. Not that I wish to undervalue the Prussian military system. It has been a means to an end; but there seems to me, neither in France nor in Germany, a sufficient desire to *quell* the unnecessary habits of smoking and tipping which so enervate us in modern days.

In no town did I remark so many ambulances, as seem lately to have existed in Heidelberg. The charming neighbourhood must have done much to restore the poor sufferers to health, and the ambulances were empty when I passed through the town. In Baden-Baden, the most exquisitely beautiful of all watering places, I did not see many wounded officers or soldiers. Gambling still continues to reign supreme there; and, what is worse, the citizens of the town are deeply grieved because it must soon be given up. Even without such unwholesome excitement, I am convinced that Baden-Baden will remain one of the great sanatoria of Europe. The waters, however, I do not think are of much value internally, but they are very hot and, consequently, hot-baths are easily obtained. The banker I had to apply to said that the Badenser were in despair, as last season was lost, and this season their best customers, the *lechtsinnige Fransosen*, would not come here. According to that gentleman, the French and Americans are less careful of their funds than either the English or the Germans; and this is my own observation, I translate by saying, that there is less fear of want in France than in any other European State.

## Correspondence.

### LONG FORCEPS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The paper you have forwarded to me containing a letter from a correspondent signing himself "Student," has for the first time directed my attention to an error, which, through misadventure, has crept into my paper on "Long Forceps," in your number of the 21st June last, and which I would otherwise have overlooked; namely, the substitution by mistake of the word "right" for "left" near the beginning of the paragraph commented on by him. I think a little careful consideration of the context would have prevented most persons from being misled by this error, or supposing it was anything but a *lapsus penne*; and it appears to me that his subsequent remarks have in no way arisen from his perception of the mistake.

In the first place let me point out that I apply the terms "right" and "left" blade according to Continental usage, being the only ones that can have a precise meaning in all positions the patient may be placed in.

Your correspondent next, ignoring altogether my statement that the blade first introduced after being passed up in front of the *rectum* is to be rotated by pronation of the right hand towards the left side of the pelvis, imagines that it has got, by what sort of process I cannot tell, into the right side; and then, following up this idea when I say that the second blade must be rotated by supination of the right hand, he says this will place both blades on the right side, which, of course, is impossible; he therefore conjectures I must have meant pronation instead of supination. This, of course, would have placed the second blade, had it been possible, on the left side where I had already placed the first.

As the rest of your Correspondent's paper proceeds on the assumption that I have throughout the paragraph been describing the second position instead of the first, I need not do more than direct him to substitute the word "left" for "right" in describing the presentation at its beginning, when he will find all his difficulties vanish.

In conclusion, let me say that, as the original mistake was mine, an explanation was due on my part, otherwise I would not have entered so much into detail for an anonymous correspondent.

I am, dear Sir, yours truly,

ANDREW INGLIS.

Aberdeen, 24th August, 1871.

### WHAT AND WHERE IS FEVER?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Well Doctor, I have seriously considered the subject of our last conversation, and I am clearly of opinion that there is no such *bonâ fide* disease as fever. I am glad you coincide with me in your opinion, and I have now to tell you that those diseases known as synochus, synocha, and typhus, are one and the same disease, the names are merely the different stages of the same disease, caused by the same poison, differing only in violence of symptoms and virulence of poison. Yes; but have you not read that great American work on fever? No; I have not. I daresay he has had a large collection of authorities to cull from, and you must observe that they all harp on the same string. What is his authority to me? Am I not my own authority; and after fifty years of practice I should think that is as good as any other. I have advanced certain opinions and ideas; if I am wrong let them refute me if they can; all I seek is the truth, the whole truth, and nothing but the truth, if I possibly can find it. They have the same means that I have, and I will only be too glad if they can point out an error.

Well, let us take an instance. Let us suppose a man in a profuse perspiration swallows a tumblerful of cold water; cold chills and all the other symptoms follow. How about your poison—your poisonous miasma? Oh! that is easily accounted for, without any poisonous miasma, as you are pleased to term it: that drink of water simply caused gastritis, or inflammation of the stomach; and as you have the cause and its sequence, all the other symptoms follow. There are many diseases accompanied by heat of skin, quick pulse, &c., &c.; many die from want of nourishment, from exhaustion. Arrowroot and such like will not support the system after all the fatty matter has been absorbed for that purpose, nature requires something stronger. I have seen brandy or whisky exert a powerful action upon the coats of the stomach when medicine failed; the stimulant gave a healthy action to the mouths of the absorbers, the circulation became invigorated, and, I feel satisfied, oxygenised; hence the stomach claimed attention; it wanted food and strong soups containing the essence of vitality—became agreeable to its refined sensibility.

It looks all very fair, Doctor, very fair indeed; but what do you say about bilious remittent fever? I do not see much difficulty there; at least, so much as you appear to apprehend. Put the liver to rights, correct its secretion, and send it by its proper and natural channel, and I think you will not have much trouble with hot skin or a quick pulse. I think, Doctor, the author I spoke of says that synocha is an inflammatory fever. It may be; look over it again, and let me know if he has pointed out where the fever and the inflammation are to be found. Nay, he has said nothing about that; he states that they are there, but he gives no locality. Then put him on the shelf. Do you know what simple inflammation is? I will give you my idea of it, though I believe volumes have been written upon it. It is simply the increased action of the arteries of a part of a locality; the blood is poured in quicker than the vein can take it up. Why these arteries take upon themselves this peculiar action I cannot say, though there may be evident cause for some, though not for all; the part becomes swollen, and the pressure on the nerves causes pain.

I think, Doctor, the closer we examine diseases the clearer they become, for nature, it appears to me, is very simple and very clear in all her actions. Yes; but there are some who prefer roundabout theories to plain facts. I have opened the abdomen of a man who died from what is known as typhus or putrid fever. In the stomach I found about four ounces of a dark fluid, sticky between the fingers, and glairy on the coat of the stomach; the head of the colon, the adjacent small intestines, and the peritoneum, were all bound together in one undistinguishable lump, and separable only by considerable violence. If cases like this are to be called and treated as imaginary disease, called fever, and every man with a particular theory of his own, when inflammation is hurrying the unfortunate patient into eternity, it is time that men should look rather more seriously at what they are doing. There are some, Doctor, who won't give up their theory, say what you like. "Convince a man against his will?" Never mind; for the present I remain yours most obedient,

ALEXANDER LANE, M.D., R.N.

P.S.—I make my opinions known, not for vanity, nor for any benefit I might derive from them, but solely for the service of my fellow-man. If I can do good I shall be most amply remunerated.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly inform me, through your journal, what fees a properly and legally qualified physician should get *per diem* for attending to give evidence at the Assizes, and who regulates or fixes the scale of fees in Ireland?

I am, yours, &c.,

Castledawson, Co. Derry.

A SUBSCRIBER.

[The fee will altogether depend on the distance to be travelled to give evidence and other circumstances. There is unfortunately no fixed fee nor any law to compel payment. The practitioner must make his bargain beforehand with the party who summonses him, but if he is called to prove a simple matter of fact irrespective of expert evidence he must honour his *subpoena* whether he be paid or not. We think £2 2s. a day should be a minimum fee.—ED. M. P.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am Medical Officer to the Fever Hospital, which is also used as a Surgical Hospital.

Last month a man was injured on the railway, and was admitted into the hospital; next day he died, and an inquest was held, to which I was called as witness. On applying for my fee the coroner said that he had no power to give me one being the medical attendant to the hospital yet I do not reside in it.

The *Lancet* says (I presume with regard to English customs), "That the Resident Medical Officer of a hospital or lunatic asylum is not entitled to a fee, but that a Workhouse Medical Attendant is."

I was obliged to go a mile from my residence to the hospital to attend the inquest—am I entitled to a fee under the circumstances?

I am, Sir, yours obediently,

X. Y. Z.

[The Medical Officer of an Hospital is debarred by Act of Parliament from receiving any fee for evidence on inquest.—ED. M. P. & C.]

WE understand that it is in contemplation to appoint a Medical Officer of Health in Cork, and that Drs. Curtis and Sullivan are candidates for the office.

WE believe there is not the least truth in the rumour to which a Dublin daily paper gave currency, that Mr. John Francis Maguire, M.P., was about to be appointed a Poor-law Commissioner for Ireland. The only means by which a vacancy in the office might possibly be created would be by the resignation of Mr. Power, but we have not the least reason to think that that gentlemen contemplates any such step.

A CORRESPONDENT, who, from the prominence which is given to his letter in the *Journal of the British Medical Association*, seems to reflect the views of the editor, gravely makes the following suggestion:—

"That each gentleman who comes to the annual general meeting should bring, or better still, send, his *carte de visite*.

"That to each *carte* should be appended the signature, or (as medical signatures are not always very legible), the calling-card of the member.

"That these frames should be suspended in some suitable position, either in the Museum or reception room, easily accessible to all.

"That to each frame should be fixed a small piece of ribbon, of the colour chosen by the Branch. That each member should also wear, attached to his button hole, a

small piece of ribbon, of the colour selected by the branch to which he belongs."

Delightful inspiration! How lofty in conception and scientific in spirit. But, perhaps, the idea is not original, for, truly, the programme reads very like the regulations for photographing of convicts, *only for the ribbon in the button-hole.*

## Medical News.

University of London.—The following are Lists of the Candidates who have passed the recent Honours Examinations:—

### FIRST B.A. ONLY.

#### ENGLISH.

##### First Class.

Summers, William (Exhibition), Owens College.

Equal { Garthwaite, Liston, private study.  
Simmons, Lawrence Mark, City of London School.

##### Second Class.

Bamford, Alfred John, New College.

Montefiore, Leonard Abraham, University Coll. and Priv. tuit.

##### Third Class.

Solomon, Joseph, Bristol Grammar School.

Cheyne, Ernest, St. Marylebone Gr. Sch. and Private study.

Fisher, William, Private study.

#### LATIN.

##### First Class.

Shaw, James (Disq. by age for Exhibition), Private study.

Thompson, Arthur (Exhibition), St. Cuthbert's College, Ushaw.

Solomon, Joseph, Bristol Grammar School.

Spokes, Arthur Hewett, University College.

##### Second Class.

Smith, Philip Vance, Univ. and Manchester New Colleges.

Sugden, Edward Holdsworth, Owens College.

Greenfield, Charles Seth, University College.

Smailes, Richard Green, Wesley College, Sheffield.

Summers, William, Owens College.

Birchenough, John Henry, University College.

##### Third Class.

Fisher, William, Private study.

Jackson, Edwin, Owens College.

#### FRENCH.

##### First Class.

Leverson, Benjamin James (Prize) University College.

Greenfield, Charles Seth, University College.

Equal { Lazarus, Edward Henry, Owens College.

##### Second Class.

Smith, Philip Vance, Univ. and Manchester New Colleges.

Jackson, Edwin, Owens College.

Spokes, Arthur Hewett, University College.

#### GERMAN.

##### First Class.

Montefiore, Leonard A. (Prize), University Coll. and Priv. tuit.

Lazarus, Edward Henry, Owens College.

##### Second Class.

Jones, Owen, Bala College.

Weber, Charles Alfred, University College.

##### Third Class.

Leverson, Benjamin James, University College.

### FIRST B.A. AND FIRST B.Sc. CONJOINTLY.

#### MATHEMATICS AND MECHANICAL PHILOSOPHY.

##### First Class.

McCann, Hugh Wm., First B.Sc. (Exhibition), Liverpool Institute.

Lewis, Thomas Crompton, First B.A., Clevedon College, Northampton.

##### Second Class.

Poynting, John Henry, First B.Sc., Owens College.

Solomon, Joseph, First B.A., Bristol Grammar School.

Pearson, James Edward, First B.A., Christ's College, Cambridge.

Fewings, James, First B.A., Queen Elizabeth's Hospital, Clifton.

### FIRST B.Sc. AND PRELIMINARY M.B. CONJOINTLY.

#### CHEMISTRY.

##### First Class.

Elwes, John Wm., Prel. Sci. (Exhibition), University College.

##### Second Class.

Richmond, James, First B.Sc., Manchester Grammar School.

Atkinson, Robert Wm., First B.Sc., Univ. Coll. and R. Sch. of Mines.

##### Third Class.

Titmas, Samuel David, Prel. Sci., University College.

Verco, Joseph Cooke, Prel. Sci., St. Bartholomew's Hospital.

Carmelley, Thomas, First B.Sc. and Prel. Sci., Owens College.

Ferrand, Edward, Prel. Sci., St. Bartholomew's Hospital.

Jones, Cyril Lloyd, Prel. Sci., Guy's Hospital.

Langley, John Geoffrey, Prel. Sci., University College.

#### ZOOLOGY.

##### First Class.

Saunders, John Chas., Prel. Sci. (Exhibition), Downing Coll. Cambridge.

Second Class.

Harrison, Chas. Edward, Prel. Sci., St. Bartholomew's Hospital. DeWatteville, Baron Armond, M.A., First B.Sc. and Prel. Sci., Univ. College.

Third Class.

Jones, Cyril Lloyd, Prel. Sci., Guy's Hospital. Edwardes, Edward Joshua, Prel. Sci., Private study.

EXPERIMENTAL PHYSICS.

Second Class.

Poynting, John Henry, First B.Sc., Owens College. Atkinson, Robert Wm., First B.Sc., Univ. Coll. and R. Sch. of Mines.

Third Class.

Richmond, James, First B.Sc., Manchester Grammar School.

BOTANY.

First Class.

Moore, Spencer Le Marchant, Prel. Sci., (Exhibition), Univ. Coll.

Third Class.

Pepper, Augustus Joseph, Prel. Sci., University College.

FIRST M.B. EXAMINATION.

ANATOMY.

First Class.

Schafer, Edward Albert (Exhibition and Gold Medal), University Col. Branfort, Henry Seymour (Gold Medal), Guy's Hospital.

Second Class.

Rayne, Charles Alfred, University College. Skerritt, Edward Markham, B.A., University College.

PHYSIOLOGY, HISTOLOGY, AND COMPARATIVE ANATOMY.

First Class.

Schafer, Edward Albert (Exhibition and Gold Medal), University Col. Skerritt, Edward Markham (Gold Medal), University College.

ORGANIC CHEMISTRY, AND MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

First Class.

Branfoot, Henry Seymour (Exhibition and Gold medal), Guy's Hospital. Firth, Charles (Gold Medal), St. Bartholomew's Hospital. Buchanan, Arthur, Guy's Hospital.

Second Class.

Rayne, Charles Alfred, University College. Dodson, Andrew, Queen's College, Birmingham. Smith, George Francis Kirby, Guy's Hospital. Schafer, Edward Albert, University College. Skerritt, Edward Markham, University College.

Army Medical Department.—The Director General of the Army Medical Department presents his compliments to the Editor of "THE MEDICAL PRESS AND CIRCULAR," and begs to enclose for insertion a List of the Candidates who have competed successfully for Appointments in Her Majesty's British Medical Service, held at the London University, on the 9th inst.—Army Medical Department, August 22nd, 1871.

MARKS.

Table with 2 columns: Name and Marks. Includes Cottle, E. W., Connolly, P. S., Dwyer, C. E., Blood, E., Faskén, W. A. D., Edge, J. D., Drury, R., Bridges, W. P., Rogers, J. G., Ash, R. V., Grant, W. C., Connolly, B. B., Barrow, H. J. W., Barrow, F. E.

A few days since we reported the death of Mr. R. M. Bernard, senior Surgeon of the Bristol Royal Infirmary, at Gwbert, near Cardigan, through falling over a precipice at that place. Strange to say, during the thunderstorm on Sunday night, the lightning struck the house where Mr. and Mrs. Bernard had been lodging, and split the bed-room in two, the bed they had occupied being burnt to a cinder. Mrs. Bernard and family had returned to Clifton on the previous day.—Western Mail.

Terrible Loss of Life.—By telegram (yesterday, Tuesday) we learn that two frightful accidents occurred on Saturday and Sunday at New York. The first was occasioned by a railway collision, twenty persons being killed and thirty seriously injured. The other a boiler explosion on board the steamer Ocean Wave, upwards of seventy persons being killed or injured.

Novel-reading a Disease.—It is curious and interesting to observe that as this comparatively new female disease has grown more virulent and intense, the old disease of scandal talking has become comparatively rare. It is, of course, physically difficult to talk scandal and to read a novel at one and the same time. Our grandmothers used to devote three or four hours every day to discussing the virtues and vices of absent friends over a dish of tea. Our sisters loll in American

chairs, and listlessly turn over a third volume; and the concentrated and slightly venomous interest which used to be excited by the peccadilloes of some half-dozen neighbours is now languidly diffused over the doings of some 400 or 500 washy creations of a washy imagination. It is, of course, possible, nay, even probable, that were novel-reading sternly suppressed, scandal and gossip would revive. Were it not for this consideration, it is an open question whether the novel traffic ought not to be dealt with as stringently as Mr. Bruce proposes to deal with the liquor traffic; whether it would not be well to enable the ratepayers of a district to limit the number of the circulating libraries, or even to close them altogether; and to place the "habitual" novel-reader under some such paternal restraint as that to which Dr. Dalrymple wishes to subject an "habitual drunkard." It is too clear, unfortunately, why it is that so many women thus waste their time and rot their minds. They read novels exactly as some young men smoke and drink bitter beer, for sheer want of something to do. And, upon the whole, a silly girl floundering about upon the sofa and reading a silly novel is a far pleasanter sight than is an unwholesome-looking youth sprawling over a bar, and mining his worthless constitution with nicotine and alcohol. Each is a melancholy specimen of brainlessness, due almost entirely to neglected education.—The Examiner.

A New Lady Doctor.—Miss Putnam has just been undergoing the very strict examinations for the doctor's degree in Paris, and has passed very creditably. This is the second case in the Paris Faculty, the innovation being made quietly, whilst elsewhere angry discussions intervene.

'Dyte' v. the St. Pancras Guardians' "Appeal Fund."—Dr. Bathurst Woodman begs thankfully to acknowledge the receipt of the following subscriptions to the Fund now being raised for the purpose of carrying on the Appeal in the above suit; the history and particulars of which, together with a report of the trial, he will be happy to forward on application:—

Table with 2 columns: Name and Amount (£ s. d.). Includes W. Marrant Baker, Esq., Dr. Barnes, Grosvenor st., Dr. Billing, Grosvenor gate, F. Gordon Brown, Esq., Dr. Andrew Clark, Cavendish sq., George Critchett, Esq., T. B. Carling, Esq., Dr. Herbert Davies, Finsbury sq., Dr. Langdon Down, Welbeck st., Dr. C. H. Drysdale, Southampton Row, Dr. Edmunds, Fitzroy sq., Peter Gowlland, Esq., Dr. Hardwicke, Maida Hill, Jonathan Hutchinson, Esq., Dr. Hughlings Jackson, Bedford place, Dr. Little, Brook st., James Luke, Esq., Dr. Morell Mackenzie, Weymouth st., C. F. Maunder, Esq., E. B. Pearce, Esq., Walter Rivington, Esq., Edward Symonds, Esq., James Teevan, Esq., James Watkins, Esq., Dr. W. Bathurst Woodman, Christopher st., A. K., One behind the Scenes, A Hater of Injustice, F.R.C.P.

Further subscriptions are earnestly and respectfully requested, and may be forwarded to Dr. Bathurst Woodman, Hon. Sec., 6 Christopher street, Finsbury square, E.C., or paid into the account of the Fund at the London and Westminster Bank, Lothbury.

Gleanings.

Test for Arsenic.

A NEW and very delicate test for arsenic has been discovered by Bettendorf. Its sensibility is so great that it is said to be capable of detecting one part of arsenic in a million parts of solution, and the presence of antimony does not affect it. In order to apply this test, the arsenious or arsenic liquid is mixed with hydrochloric acid until the fumes are apparent; thereupon stannous chloride is added, which produces a basic precipitate, containing the greater part of the arsenic as metal, mixed with stannic oxide.—Medical and Surgical Reporter.

## Bromide of Iron in Seminal Emissions.

BROMIDE of iron is recommended by Dr. N. H. Norris, of Beloit, Wis., as almost a specific in involuntary seminal emissions and spermatorrhœa. He has given it three times daily, an hour before or after meals, in doses of three to five grains, rubbed up in a little syrup; at bedtime a sufficient quantity is given to produce good refreshing sleep, free from lascivious dreams, for which purpose ten grains are usually sufficient, but as much as twenty grains have been given without injury. — *Northwestern Medical and Surgical Journal*, April, 1871. — *American Journal of Pharmacy*.

## NOTICES TO CORRESPONDENTS.

TO OUR SUBSCRIBERS.—Gentlemen who have not paid their subscription for last year are respectfully reminded of the omission. The Publishers would also be much pleased to receive arrears of subscriptions due for several years previously, which, in too many instances, remain unpaid, notwithstanding frequent applications for settlement.

NOTICE.—Subscribers are respectfully reminded that payment by P.O.O., or crossed cheque, is the most convenient and safest mode of remittance. Stamps are unfortunately too easily disposable by dishonest persons.

All valid receipts are given upon printed forms. Subscribers and advertisers are particularly cautioned against making any payments without the production of such a receipt. Cheques or P.O.O. should be made payable in England, to A. A. Tindall; in Ireland, to A. H. Jacob, M.D.; in Scotland, to MacLachlan and Stewart.

## NEW READING CASE.

In consequence of the postal restrictions as to stitching the Journal, improved reading cases with twenty-six strings to hold one volume can now be obtained through any bookseller in town or country, price two shillings. The advantages to subscribers are, that each number when received by post has but to be slipped into the cord, no stitching or pinning being required. The Journal is kept flat for reading, and each volume complete for reference. The same portfolio can be used for successive volumes where desired.

## RECENT NUMBERS OUT OF PRINT.

Full price will be given for THE MEDICAL PRESS AND CIRCULAR of November 23, 1870, and February 1, 1871, on receipt of same with name and address of sender, at the London offices of this paper, 20 King William street, Strand.

F. J. will find the information he asks for respecting Dr. Chapman's Treatment of Cholera in Vigla's wards, at pages 224, 225 of Dr. Chapman's work on "Diarrhoea and Cholera," published by Trübner & Co.

H. A. ALEXANDER.—We have every reason to believe that the Society for Organising Charitable Relief is well conducted by honourable men.

We must beg the indulgence of several gentlemen whose contributions are in type, and only postponed again through the lengthy proceedings of the annual meetings occurring at this season, and for a report of which all our readers look. We trust that we have fairly met the wishes of our supporters.

CASES, PAPERS, LETTERS, &c., have already been acknowledged as in type by Mr. Teevan, Dr. Luther, and others. We hope, now our reports of societies are over, to insert them forthwith.

MR. BRADLEY'S valuable paper shall appear as early as possible.

HOMŒOPATHY.—The conclusion of this criticism is postponed till next week.

WAGGA-WAGGAGRAPH.—A correspondent wants to know if this is a new instrument for any Medical purpose. We believe not. We have seen an advertisement calling it a "Speaking Indicator for Carriages." Perhaps it is something to enable the person in a carriage to communicate with the coachman. If so, it will only be useful to those Medical men who keep broughams.

Received as we were going to press "The Contradictions of Dr. George Johnson's Theory of Treatment in Cholera," by R. Hianslip Sers, M.R.C.S. "Peculiar Pathological and Physiological Symptoms occurring in one of the Lower Animals," by Mr. J. Moir.

## APPOINTMENTS.

- BOWRING, G., M.R.C.S.E., Hon. Surgeon to the Royal Infirmary, Manchester.  
 CEELEY, R. W., M.R.C.S.E., Assistant Medical Officer to the Devonshire Lunatic Asylum, Exminster.  
 CLAYTON, Dr. J., Visiting Physician to the Banff District Lunatic Asylum.  
 FORDHAM, J. W., L.R.C.P.Ed., Resident Accoucheur to the London Hospital.  
 MAJOR, H. C., M.B., C.M., Clinical Assistant at the West Riding of Yorkshire Lunatic Asylum, Wakefield.  
 MANSON, A. J., M.D., Visiting Physician to the Banff District Lunatic Asylum.  
 MATHIWS, G. C., L.R.C.P.Ed., L.R.C.S.I., Medical Attendant to the Royal Irish Constabulary, Moate, co. Westmeath.  
 PARTRIDGE, T. B., M.B., Assistant-Physician to the Metropolitan Free Hospital.  
 PORTER, R. H., L.A.H.Dub., L.M., Apothecary and Accoucheur to the Fever Hospital and House of Recovery, Cork street, Dublin.  
 PURSER, J. M., M.D., L.K.Q.C.P.I., Physician to the City of Dublin Hospital.

## Deaths.

AEPTHORPE.—On the 29th of May, at Melbourne, Australia, W. Aepthorpe, L.S.A.L., formerly of Princes street, Leicester square, aged 60.

CASEY.—On the 21st inst., Thomas Casey, M.D., of St. Albans, aged 76.

DAY.—On the 9th inst., at Bath, W. M. H. Day, M.R.C.S., Assistant Medical Officer Bristol Lunatic Asylum.

MANN.—On the 14th inst., at St. Asaph, R. Mann, M.R.C.S.E., late of Manchester, aged 81.

PERKINS.—On the 17th inst., at St. Sidwells, Exeter, John Shirley Steele Perkins (of aneurism of the abdominal aorta), aged 26.

THOMAS.—On the 1st of June, suddenly, at Collins street, East Melbourne, Australia, David John Thomas, M.D., F.R.C.S.E., formerly of Llwyn-y-Berlan, Carmarthenshire, South Wales, aged 58.

## Advertisements.

## CHARING CROSS HOSPITAL SCHOOL OF MEDICINE.

The WINTER SESSION will commence on MONDAY, the 2nd of October.

An Introductory Address will be given by T. HENRY GREEN, M.D., at 8 p.m.

The New School Buildings afford every convenience for study, and the increased hospital accommodation has greatly augmented the means of clinical instruction.

Three Resident Medical Officers are selected from among the Senior Students every six months.

Fees, including Matriculation, £76 5s., which may be paid in five instalments.

Further information and prospectus may be obtained by application to the Dean, at the Hospital.

A. J. POLLOCK, Dean.

## ST. THOMAS'S HOSPITAL.

THE MEDICAL SESSION for 1871 and 1872, will commence at the NEW HOSPITAL on the Albert Embankment, Westminster Bridge, S.E., on MONDAY, the 2nd OCTOBER, 1871, on which occasion an INAUGURAL ADDRESS will be delivered by Mr. LE GROS CLARK, at Two o'clock, after which the DISTRIBUTION OF PRIZES will be made by SIR FRANCIS HICKS, Treasurer.

Students entering have the option of paying £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105, at once of becoming perpetual Students.

## PRIZES &amp; APPOINTMENTS FOR THE SESSION.

First Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, and £5.

THE WM. TITE SCHOLARSHIP, founded by Sir Wm. Tite, C.B., M.P., F.R.S., the proceeds of £1,000 Consols, tenable for three years, is awarded every third year.

Second Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, £5. The DRESSERSHIPS, and the CLINICAL and OBSTETRIC CLERKSHIPS.

Third Year's Students. WINTER PRIZES—£20, £15, and £10. MR. GEORGE VAUGHAN'S CHESELDEN MEDAL. THE TREASURER'S GOLD MEDAL. THE GRAINGER TESTIMONIAL PRIZE. THE TWO HOUSE PHYSICIANSHIPS. THE TWO HOUSE SURGEONIES. THE RESIDENT ACCOUCHEURSHIPS. TWO MEDICAL REGISTRARSHIPS, at a salary of £40 each, or one at £50, are awarded to 3rd and 4th years' Students, according to merit.

## MEDICAL OFFICERS.

Honorary Consulting Physicians.—Dr. Barker and Dr. J. Risden Bennett.

Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Murchison, Dr. Barnes, Mr. Le Gros Clark, Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. Liebreich, Dr. Stone, Dr. Ord, Dr. John Harley, Dr. Payne, Dr. Gervis, Mr. MacCormac, Mr. Francis Mason, Mr. Hy. Arnott.

Medicine.—Dr. Peacock and Dr. Murchison. Surgery.—Mr. Le Gros Clark and Mr. Sydney Jones. General Pathology.—Dr. Bristowe. Physiology and Practical Physiology.—Dr. Ord and Dr. John Harley. Descriptive Anatomy.—Mr. Francis Mason and Mr. W. W. Wagstaffe. Anatomy in the Dissecting Room.—Anatomical Lectures.—Mr. Rainey and Mr. Wm. Anderson. Chemistry and Practical Chemistry.—Dr. A. J. Bernays. Midwifery.—Dr. Barnes. Practical and Manipulative Surgery.—Mr. Croft and Mr. MacCormac. Physics and Natural Philosophy.—Dr. Stone. Materia Medica.—Dr. Clapton. Forensic Medicine and Hygiene.—Dr. Stone and Dr. Gervis. Comparative Anatomy.—Mr. C. Stewart. Ophthalmic Surgery.—Mr. Liebreich. Botany.—Dr. Wals Hicks. Dental Surgery.—Mr. J. W. Elliott. Demonstrations Morbid Anatomy.—Dr. Payne. Mental Diseases.—Dr. Wm. Rhys Williams. Geographical Distribution of Diseases in England and Wales.—Mr. A. Haviland.

R. G. WHITFIELD, Medical Secretary.

T. B. PEACOCK, M.D., DEAN.

# Irish Poor-Law Intelligence;

UNDER AUTHORITY OF THE

## IRISH MEDICAL ASSOCIATION.

[THE Editor of this Journal is aware that there exists in the practical working of the Poor-law and Medical Charities systems throughout Ireland a great absence of uniformity as regards details, and that the Poor-law Medical Officers at large, and the Irish Medical Association as representing them, are very imperfectly informed on many matters of practice in the working of the medical relief of the poor. It would, obviously, be of great advantage to the Poor-law Medical Officers that more perfect information on such points should be forthcoming, inasmuch as it would put individual officers in the position to profit by the experience of their colleagues, and would make it possible for the Irish Medical Association to suggest a remedy for many disadvantages which arise from inexperience of the working of the system elsewhere.

In order, therefore, that the Poor-law Medical Officers shall be put in closer communication, and shall profit by the daily experiences of their brethren, it is intended to take, as it were, a weekly *plebiscite* through the pages of this Journal. In each issue of the Journal henceforth a series of questions on some one point of Poor-law practice will be submitted to its readers, in such a form that the queries can be readily and briefly answered by each subscriber, and the page containing them retransmitted to the Editor. These answers will be carefully collated, practicable suggestions noted, the remedy for discomforts or grievances sought for in the existing laws and regulations, and the result published in the JOURNAL OF THE IRISH MEDICAL ASSOCIATION, if possible, the following week.

It will be possible, under this arrangement, for Poor-law Medical Officers to give utterances to their wishes and suggestions without reserve, inasmuch as the replies being unsigned, the Editor or any other person will remain in ignorance of the identity of the writer; and, it is thus hoped, that a more open and confident exposition of the merits and demerits of the Irish Medical Relief system will be achieved, than could be obtained by any other means, and that the intimate inter-communication of such facts will result in much benefit to those most interested.]

### THREATENED APPROACH OF CHOLERA.—THE NAAS BOARD OF GUARDIANS.

A LETTER was read from the Town Clerk of Naas, calling the attention of the guardians to a resolution passed by the Naas Town Commissioners at their late meeting, when the Town Inspector reported that certain sewers of the workhouse emptied themselves into a river much used by the inhabitants of the town.

The master stated, in reply to the board, that the sewers did empty themselves into the river, and that to avoid that it would be necessary to make a cesspool on the workhouse grounds.

The board unanimously directed that the master should make a report on the next board day as to the best place to have the cesspool made.

It was proposed, and passed unanimously—"That the Board of Guardians would impress most strongly upon all the committees of dispensaries in the union the absolute necessity of frequent inquiries through the medical officer as to the state of health of their districts. Also to

order the various inspectors of nuisances to be instructed to use the utmost vigilance in an immediate inspection of all drains and cesspools in their districts, and free use of disinfectants and whitewashing of houses inside and out, and thus as far as lies in the power of the dispensary committees and medical officers of the districts prevent the visitation of cholera in the union; the committees of dispensaries to supply lime and the use of whitewash brushes gratis to the poor of the several districts."

### BELFAST BOARD OF GUARDIANS.

#### INFECTIOUS DISEASES.

The Clerk read the following communication:—

"Poor-Law Commissioners' Office, Dublin,  
18th August, 1871.

SIR,—The Commissioners for administering the Laws for the Relief of the Poor in Ireland have had before them a minute of the Board of Guardians of the Belfast Union, on the 8th inst., referring to them to decide whether or not the sanitary inspector of the Town Council, within the Borough of Belfast, is the proper officer to carry out a magistrate's order for the removal of persons suffering from infectious diseases within the Act of 1866, or to whom such magistrate's order should be directed under the 26th sec. of the 29th and 30th Vic., cap. 90; and, in reference thereto, the Commissioners desire to state that the duty of the Board of Guardians does not, in the opinion of the Commissioners, commence in regard to cases of contagious diseases occurring within the district of another nuisance authority, and falling within the provisions of the 26th sec. of the Sanitary Act, until the removal of the patient to the hospital has actually been effected. At the same time, the Commissioners think that in any case where the magistrates may have made an order, with the consent of the guardians, for the removal of any case of contagious disease to the fever hospital of the Workhouse, and the patient is willing to be removed, the services of the relieving officer shall be given the same as they would be in any ordinary case.

(By order of the Commissioners),

"B. BANKS, Chief Clerk.

"The Clerk Belfast Union."

### SMALL-POX IN LONDONDERRY.

THERE has been one case of small-pox under treatment in the Waterside Fever Hospital during the past fortnight. The patient, George Richardson, a seaman, was admitted from a coal vessel named the Gertrude, from Maryport, which had arrived in this port. The man is now convalescent, and wished to leave on Saturday last in order to sail in that vessel. We are not aware what precautions, if any, are adopted at Derry for the prevention of the spread of contagion by vessels entering this port; but we are informed that at Maryport lately, the very place from which the Gertrude sailed, an Irish sailor affected with the same disease was not allowed to land,

and was refused hospital accommodation. The sick man was confined to the hold for some time, and at length died. It is said that the Irish Poor-Law Commissioners are at present investigating the circumstances of the case.

### DISINFECTION OF THE RIVER LIFFEY BY CHLORALUM.

DURING the last few days, the Public Health Department of the Corporation of Dublin have been occupied in disinfecting the foreshores of the Liffey, which bisects their city. This river has long been notorious as a source of odours as vile and as numerous as those which offended the nose of the poet Coleridge during his celebrated visit to Cologne. The foreshores are left high, but not dry for several hours daily, and during this time they pale, in warm weather especially, a very bad odour. They have now been cleansed of the foul deposits of mud and filth, and disinfected by chloralum, at the rate of one pound per twenty-five square yards. The experiment proved, says the *Chloralum Review*, perfectly successful.

### INVESTIGATION AT THE ENNISCORTHY WORKHOUSE.

ON Saturday, the 15th instant, Captain Robinson, Poor-Law Inspector, held a sworn investigation in the Board Room of the Enniscorthy Workhouse, for the purpose of examining into "the statements made by Dr. O'Rourke in his communication to the Poor-Law Commissioners, relating to the expenditure for medicines in the Enniscorthy Dispensary." During the investigation the following gentlemen were present:—Rev. J. L. Furlong, Adm., George C. Roberts, J.P., T. G. Cranfield, J.P., L. Doyle, J. Cullin, L. W. Corcoran, Dr. O'Rourke, Dr. Goodisson, John Deathe, William Rudd, Samuel Davis, Matthew Furlong, P. M. Cooke, John Flynn, W. Cooke, &c.

Dr. O'Rourke was the first witness sworn.—He said that on Monday, the 3rd April, he attended a meeting of the Town Commissioners in the Market House; that during the meeting Mr. Keohler came into the room and remarked "that it was a large meeting." The chairman told him it was a meeting of the Commissioners, when Mr. Keohler said he had been summoned to attend a meeting of the Dispensary Committee, and produced the summons. That was the first intimation witness had of the meeting; it was stated in the circular that it was a "special" meeting to grant sick leave to Dr. Cranfield, who was then very ill; asked Mr. P. Cooke, hon. secretary of dispensary committee, who was present, why he (Dr. O'Rourke) was not summoned; Mr. Cooke replied that he had only summoned four, Mr. Mathew Furlong, Mr. Keohler, Mr. Thomas Sinnott, and Mr. James Moran, as they were the nearest to him; witness remained for the meeting, at which there were seven persons present, and took part in the proceedings; a person was appointed to replace Dr. Cranfield; heard Mr. Cooke say there was medicine ordered; made no objection then, and left the meeting; at a subsequent period seeing the quantity of medicine ordered, and considered it in excess, I called attention to it, because at the time the contract was taken it was held out as an inducement that the contractor being local the medicines could be obtained in small quantities as they were wanted.

Captain Robinson here produced an estimate for medicine, signed by Mr. Roberts, as chairman, and Dr. Goodisson, as medical officer.

Dr. O'Rourke—I did not see that estimate.

Mr. M. Furlong, member of the dispensary committee, said he was present at the meeting when that estimate was produced.

Dr. O'Rourke—I did not see it. The estimate I speak of was on the minute book.

Captain Robinson—Perhaps you had left. Will you

now state the quantities of medicines you consider to be in excess?

Dr. O'Rourke—16lbs. of aromatic spirits of ammonia; 5½lbs. of chloroform; 3½lbs. compound tincture of bark; 3½lbs. white precipitate ointment; 8lbs. of hippo wine; 5 gals. of cod liver oil; 4lbs. paragoric elixir; 4lbs. magnesia.

Here some remarks were made as the numbers and estimate from which these items were taken.

Captain Robinson—The list is revised every year, and we must confine ourselves to the present one.

Dr. O'Rourke then continued to enumerate the medicines as follows: 28lbs. sulphur; 28lbs. cream of tartar; 6 pints liquor of potash; 42lbs. castor oil; 5 gals. rectified spirits of wine, and 40lbs. of treacle.

Captain Robinson—I think that is enough for our purpose.

Dr. O'Rourke—I consider every article in the estimate was in excess.

Captain Robinson—Now as to the medicines not enumerated in the catalogue, what are they?

Dr. O'Rourke—4oz. liniment of iodine; 4oz. liniment of belladonna; 8oz. liquor of extract of bark; 1lb. Long's liquor of ergot; 4lbs. citron ointment; 7 gross of Dally's corks; quarter of a yard of gutta percha tissue; and 12 vaccination points.

Captain Robinson—Will you detail the conversation you speak of, as having taken place with Dr. Goodisson?

Dr. O'Rourke—When speaking with Dr. Goodisson, I called his attention to the estimate for medicine on the minute book, and he said he was no party to that estimate; subsequently he (Dr. G.) explained, and said that many of the articles were used previously, but he did not say that he had signed the amount; and farther that he was getting some of the medicines for some time past, and that the estimate was to cover those previous supplies. Dr. Goodisson did not say upon what orders the medicines had been previously supplied. Heard from the porter of the fever hospital that Mr. P. M. Cooke, and Mr. W. Cooke, the contractor, dispensed medicine at the dispensary.

Captain Robinson (addressing the master of the union),—Let the porter be sent for at once, and let him bring his book.

Mr. Corcoran—And let no person have any communication with him.

Captain Robinson—with reference to the relationship of the Messrs. Cooke?

Dr. O'Rourke—The contractor is a son-in-law of the secretary; believe they live in one house; they have a house in Gorey.

Mr. Flynn—What name is over the house in Gorey?

Mr. P. M. Cooke—"P. M. Cooke and Co." That will be explained by-and-by.

Captain Robinson—Where is the medicine supplied from?

Dr. O'Rourke—Cannot say.

To Mr. Corcoran—I have no fault whatever to find with the quality of the medicine.

Dr. O'Rourke was then asked did he not himself recommend the contract to be taken from Mr. Cooke. He said not—that on the day the tenders were considered by the Board he was summoned, along with the other Medical officers of the union, to consider the Medical tenders, and whilst we were doing so, the Board resolved to give it to Mr. Cooke as a local contractor.

Mr. W. Rudd—I was present at that meeting, and I think you recommended Messrs. Boileau.

Dr. O'Rourke—Only so far as they were the lowest.

Mr. Flynn—What was the amount of medicine used in the workhouse last year?

Dr. O'Rourke—About £2. I prepare all my own medicines, and I only apply for the simples.

Mr. Flynn—And when the medicines were got from a Dublin establishment it used to be £7 or £8.

Mr. Corcoran—Where do you get your medicines from?

Dr. O'Rourke—From Mr. Cooke's establishment; I have no notion of paying for them out of my own pocket.

It was then suggested that Dr. O'Rourke should be asked why he brought those charges against the Medical officers.

Mr. Corcoran—Oh, the doctor has brought no charges against the Medical officers.

Dr. O'Rourke—No, indeed, I have not.

In reply to Captain Robinson, the doctor stated that he recollects a large supply of medicine being ordered from Leslie's, of Dublin, for the Enniscorthy Dispensary, but a great part of it had to be returned; I was not present when that order was given, but, but I think it was subsequently brought before the Board of Guardians; I did not make any written complaint on the matter.

Dr. Goodisson sworn—The estimate for medicine now produced was prepared by me, and is in my handwriting. Sent it to the hon. secretary before the meeting of the 3rd of April. All the figures are in my handwriting. The estimate was made out and signed by me in the ordinary way. It is usual to have them signed by both Medical officers, but Dr. Cranfield was sick at the time. Some of the articles included in the estimate had been obtained by Dr. Cranfield and myself previously to its being made out. We had no authority from the Board to order them. The doctor here named the articles not included in the regular catalogue which had been ordered previous to, and at the time of, making out the estimate. He considered the selection of a local contractor by the Board of Guardians was to enable us to make the small orders at any time we were in want of them. The orders were always sent to Mr. Cooke at Enniscorthy. The doctor then named several medicines that he had occasion to send for without laying an estimate before the committee. The articles not named in the catalogue were required for special purposes; he had no recollection that they were ever ordered before.

Mr. P. M. Cooke—In the order to Mr. Leslie for November, there is one pint of Long's liquid of ergot mentioned.

Dr. Goodisson—It is our usual practice to make out only two estimates in the year—in October and April—and that has been our practice for years; since Mr. Cooke became contractor we had only sent him one previous estimate.

Captain Robinson—Can you state anything with respect to the charge of the Messrs. Cooke dispensing medicines at the dispensary.

Dr. Goodisson—I admit that Mr. P. M. Cooke attended for me at the dispensary on two occasions and dispensed medicines; the contractor never did; on both occasions I was urgently called away, one of them being a summons to attend at Gorey; there was no authority from the committee for Mr. Cooke to dispense the medicine, and I never made a report of it; Mr. Cooke is a qualified apothecary only.

To Dr. O'Rourke—Every entry in the estimate was made by me before the meeting; sent the estimate specially to the secretary before the meeting in order that it might be laid before the meeting; could not tell why I sent it to a special meeting, and was not aware that I was acting wrong, or I should not have done it.

Mr. Flynn wished to know the actual cost of the medicine ordered that was not mentioned in the catalogue. It would be satisfactory to know.

Dr. Goodisson—About 30s. or £2.

Mr. Corcoran—Was there not a saving of £20 to the union last year by Mr. Cooke's contract. Can you give us the exact figures.

Dr. Goodisson—Mr. Leslie's bill the last year of his contract was £83 11s.; Mr. Cooke's was £63 19s. 1d.

To Captain Robinson—Recollects Dr. O'Rourke speaking to me about the estimate, but I did not consider the

time or place fitting for the conversation, and I rather evaded answering his question; did not intend to convey to him that I knew nothing of the estimate.

Dr. O'Rourke—I brought the transaction before the committee a few days after the occurrence, and I made the same statement then that I did to-day.

Dr. Cranfield desired to be sworn, as he thought he was better able to explain why some of the medicines not in the catalogue were ordered, as some of them were for cases under his own immediate care. On being sworn, he entered into a medical explanation of each article separately, and said that the whole of the Belladonna was got for one patient, that had disease of the bladder, and he was happy to say it made a perfect cure; the liquid extract of bark we get in order to save time when preparing an infusion of bark on sudden emergencies; Long's liquor of ergot we are in the habit of getting for some time, because the ergot usually supplied becomes inert, and Long's preparation is now used by medical practitioners generally; the citron ointment we have been always using, and it ought to be on the list; the corks require no explanation as we always got them—they are a particular kind used by medical men; the gutta percha tissue and vaccination points we have also been in the habit of using. With regard to the other medicines the district is very large, with three dispensaries, and the order is not unusually large, nor so large as when we obtained our medicines from Dublin; the district being so large it requires a considerable amount of medicine to supply us. For instance a patient might consume a gallon of cod-liver oil in a month. Formerly when we were run out of medicine we had to borrow from Mr. Cooke and Dr. O'Rourke, and paid them back when we obtained our supplies.

Dr. O'Rourke.—I would always most gladly give it.

Mr. Flynn.—It would not be right to let a person die for a little medicine.

Dr. Cranfield.—We never reported it to the committee, nor did we think it necessary to do so, as we did it for the public convenience.

To Mr. Robinson—Whenever we obtain any medicine from Mr. Cooke before the making up of the estimate we always allow for it, and he includes it in his bill.

Dr. Cranfield then entered into a detailed explanation of some of the items which appeared to be in excess, and in reply to Captain Robinson said, Mr. William Cooke, the contractor, compounded medicine for me on two or three occasions at the Dispensary, but always during my presence; the day Dr. Furlong was appointed to act for me, Mr. Cooke went to the Dispensary to point out the medicine to that gentleman; Mr. P. M. Cooke has been at the out-dispensary (Oilgate) two or three times for me, but not for the last two or three years. He did not act on the authority of the committee, whenever he did go it was in case of some sudden emergency; never made any report of this to the committee; Mr. Cooke is only a qualified apothecary.

Dr. O'Rourke.—He is a qualified apothecary and accoucher, and the latter is acknowledged by the Commissioners as one of the qualifications.

Dr. Cranfield.—The medicines not mentioned in the catalogue supplied by Mr. Cooke is only charged cost price, that was not so with the former contractors, as they always charged double the price for such articles.

Mr. P. M. Cooke sworn.—Is honorary secretary to the Enniscorthy Dispensary Committee; the requisition convening the meeting, to the best of my recollection, contained a notice of the appointment of a substitute for Dr. Cranfield, and to transact other business; the chairman (Mr. Roberts) called on me between 9 and 10 o'clock on Sunday night, and requested me to summon a meeting for the next day; at that time I had a knowledge that Dr. Goodisson would put in an estimate for medicine; cannot say whether I put in an estimate for medicine; cannot say "ordinary" meeting.

Dr. O'Rourke.—The circular I saw with Mr. Keohler said it was "to appoint a substitute for Dr. Cranfield during his illness."

Mr. Cooke.—I am sure I never mentioned Dr. Cranfield's illness, but it was said to receive an application.

To Captain Robinson—The words were, I believe, "an application from Dr. Cranfield, and other business." Had heard some time before that Dr. Goodisson had an estimate to put in; issued the circulars on Monday to four members only, and those the nearest me, as I had only an hour or so to do it; it was want of time that prevented me summoning more, neither did I think it necessary, as I thought that number would do; I am in the habit of summoning the whole committee, and seldom more than four or five attend. Mr. William Cooke, the contractor, and I reside in the one house; he is at present here in consequence of my ill health. About two years ago Dr. Cranfield was attending me, and was not satisfied with my foreman, and he advised me to get down my son-in-law; the business at Gorey is solely carried on by him; I have nothing whatever to do with the establishment in Gorey; I had to do with it; the reason my name was put up over the Gorey establishment was, that at the time my son-in-law purchased that place he was not a qualified apothecary, and I gave him the use of my name; I have no interest now directly or indirectly in that concern; did not think it necessary to alter the name after my son-in-law was qualified, as I think it was a benefit to him; handed the place over to him about three years ago, when he took out his diploma; he is not concerned in the business here (Enniscorthy) with me, he is only here as my assistant; he is better than two years with me, and has remained with me ever since, going to Gorey about once a week; the tenders in Gorey are made out in the name of "P. M. Cooke and Co.," but I have nothing whatever to do with it; I supply a good deal of medicine from my establishment for the Enniscorthy Dispensary.

Mr. W. Cooke.—I get the order, and Mr. P. M. Cooke supplies me with the medicine at cost price.

Mr. P. Cooke.—I have no profit on it.

Dr. O'Rourke.—Did you not say at the meeting it was to save expense that you did not summons any more.

Mr. P. Cooke.—I have no recollection of saying so.

To Mr. Corcoran—I had no object whatever in omitting to summon Dr. O'Rourke; do not recollect that I ever mentioned it was to save expense that I did not summon a full meeting; I have no interest whatever, directly or indirectly, in the medical contract.

Mr. Flynn.—That is very important.

Mr. William Cooke sworn.—I am contractor for medicines for this union; I have not the slightest interest in the establishment at Enniscorthy; I am sole proprietor of the establishment in Gorey; supplies the Enniscorthy Dispensary with medicines out of Mr. P. Cooke's establishment in this town, and none of them from Gorey; do that in order to expedite the delivery of medicine to this union, as they are often required in a hurry; purchase the medicines from Mr. P. Cooke at cost price, and we keep a separate account of it; he has no profit whatever from the medicine so sold to me.

Mr. Roberts, J.P., sworn—I called on Mr. P. M. Cooke, the secretary of the Dispensary Committee, on Sunday evening, the 2nd April, in consequence of an interview I had with Dr. Cranfield; the Doctor was very unwell, and he wished me to have a meeting summoned to appoint a substitute, as there was a great deal of business in his district; requested Mr. Cooke to summon the members in the town, as there was no time to send to the country; presided at the meeting next day; the estimate for medicine was laid before me, and was signed by me before the meeting broke up; the date on the estimate is also in my handwriting; I understood it to be a special meeting for a special purpose, but then it has been a practice at such meetings to transact whatever business came before them; that was always done by the committee, and they did not know they were violating any law. Dr. O'Rourke complained of not having received any notice for that meeting, and I explained that it might have been in the hurry of the moment that his name was omitted;

and Mr. Cooke explained that there was no discourtesy intended. There was no objection to the meeting, and we transacted the business, Dr. O'Rourke taking part in it, having either proposed or seconded a resolution.

This concluded the investigation.

#### Hypodermic Use of Ergot in Uterine Disease.

Dr. VON SWIDERS strongly recommends subcutaneous injection of ergot in uterine affections, especially chronic metritis and metrorrhagia. Severe bearing-down pains are said to be often produced, coming on in from a half to one hour. His formulæ are, where a rapid effect is desired: Aqueous extract of ergot, 2.5 parts; rectified spirits and glycerine, each 7.5 parts;—Aqueous extract of ergot, 2 parts; rectified spirits, 5; glycerine, 10 parts. Where a slower and slighter action is desired: Aqueous extract of ergot, rectified spirits, each 2.5 parts; glycerine, 12.5 parts;—Aqueous extract of ergot, 1 part; rectified spirits, 1.5; distilled water, 4.5; glycerine, 3 parts.—*Wiener Medizinische Wochenschrift*, January, 1871.

#### Clitoridectomy.

Dr. J. P. WHITE, of Buffalo, N. Y., (*American Journal of Insanity*), extirpated the clitoris in an epileptic girl, aged twenty years, who was addicted to onanism. The habit was broken up entirely. It is now about three years since the operation; the habit has not returned, nor have the epileptic paroxysms reappeared. He has operated in two other instances. In one case the paroxysms were postponed a month or two, but the epilepsy was not interrupted. Two of the cases were young girls, where the habit of masturbation was established at boarding school. Dr. White would suggest the substitution of the division of the pubic nerves subcutaneously for the more offensive mutilation of clitoridectomy. This operation would be far less disgusting, and may afford equal relief. In some instances which have come under his observation, the patients were wonderfully susceptible to the influence of this peculiar excitement; and upon applying the finger to the clitoris, it acted almost like a galvanic shock.—*Med. Record*.

#### Castor Oil made Palatable.

A CORRESPONDENT of the *Boston Medical and Surgical Journal* suggests that this article of the Pharmacopœia may easily be made palatable by the employment of glycerine as an excipient; in fact, the dose will be found as "sweet as honey," and devoid of any unpleasant taste:

R—Glycerine (puriss)  
Ol. ricini, aa ʒij.  
Ol. cinnamomi, ℥ jv.—M.

The ol. cinnam. should be rubbed up with the glycerine, and the ol. ricini then added, and the whole well mixed, by being shaken when used. In larger doses, lessen the proportion of the glycerine.

#### Tracheotomy in Croup.

DR. GUERSANT (*Medical News and Library*) gives the subjoined indications necessitating the operation of tracheotomy:

The first indication is, that the suffocation and asphyxia from which the patient suffers shall be permanent, and without intermission.

The second indication is, that the disease shall be local and not general. In the former state the patient is in the most favourable condition, in the latter there is but little chance of success. In fact, if false membranes exist in the nose, or behind the ears, or, as is frequently the case, there is ulceration even in the vulva; if there are many enlarged glands under the jaw, and if the urine is albuminous, it is necessary for the operator to know that he has very little or no chance of success.

The third indication is, that the patient shall be at least two years old. The number of successful operations performed prior to that period has been very small, and the cases are only exceptional in which tracheotomy has succeeded in children of six months, a year, and eighteen months; and yet the successful result achieved by M. Scoultettin on a child of six months, and that of M. Maslieurat Lagémar, induce him not always to decline operating on children under a year old.—*Med. Record*.

### DIARRHOEA AND CHOLERA: THEIR SUCCESSFUL TREATMENT BY MEANS OF THE SPINAL ICE-BAG.

A SUMMARY RECORD OF CASES AND RESULTS.

By JOHN CHAPMAN, M.D., M.R.C.P., Physician to the Farringdon Dispensary.

The fundamental principles on which the treatment described and exemplified in the following pages reposes may be stated summarily as follows:—

#### Negative Principles.

1. That though, in exceptional cases, diarrhoea as well as cholera, may present itself associated with the presence of a blood-poison, neither the one nor the other is, as a general rule, the product of such a poison;\* and that there are very strong and very numerous reasons for believing that the hypothetical so-called "cholera-poison," of the existence of which no proofs have ever been adduced, exists only in the imagination of certain pathologists.

2. That the existence of the so-called "cholera-germs,"† which are alleged to be produced and disseminated in terrific abundance from the gastric and intestinal discharges of cholera patients, has never been shown to be probable by even one particle of evidence, and that there are numerous and very strong reasons for believing that they are creations as exclusively hypothetical and subjective as is the imaginary "cholera-poison" itself.

3. That the pathological changes constituting the phenomena of cholera are not referrible, as suggested by Dr. Gull, "to an early and severe depression," or "extreme exhaustion of the great ganglionic nervous centres in the abdomen;" that "the vital energy of the nerves distributed to the respiratory, the circulatory, and the secreting

organs, is either uncommonly depressed or entirely annihilated, is" not "shown by the nature of the characteristic symptoms constituting the malady," as it is affirmed to be by Dr. Copland; and that a vast array of authentic facts disproves the assertion of Dr. Goodeve that, "in the intestines a sort of paralysis of the smaller arteries and capillaries seems to exist, much as occurs in the sections of the sympathetic nerve in the neck in Bernard's experiments."

4. That cholera does not "travel" from place to place, as in almost every history of its manifestations it is said to do; that it can originate *de novo* in any place in which certain definable conditions co-exist; and that it may even be generated afresh, without the aid of "cholera-germs," and without any contact or relation of any kind with cholera patients, by either the stupid conduct or conscious efforts of man himself.

5. That, though in the focus of a cholera epidemic the influence generating the disease is often felt by persons who are not actually attacked by it, and though when that influence tends to render all within the sphere of it liable to attack, the emanations of cholera patients, like any other foul or unwholesome emanations, may operate as exciting causes of the disease, whereas they would not do so under other circumstances, nevertheless, cholera is neither infectious nor contagious; and that the costly and vexatious international regulations, often involving great suffering, by which Governments attempt to resist invasions of the disease, are no defence whatever against its attacks, whereas its development and continuance are, probably, often favoured by the enforcement of the laws of quarantine.

#### Affirmative Principles.

1. That both diarrhoea and cholera, however induced, are essentially and invariably disorders of the nervous system.

2. That the nature of the summer diarrhoea of temperate climates, and that of the diarrhoea which often precludes, and indeed constitutes the initial stage of, cholera in tropical climates, are essentially identical.

3. That the summer diarrhoea of temperate climates, the so-called cholericine, English or European cholera, and Asiatic cholera, are also essentially or etiologicaly one

\* The doctrine that the blood of cholera patients is poisoned is held by Parkes, Goodeve, Johnson, and a host of other pathologists.

† The "cholera-germ" theory was held by Dr. Snow, and has been most zealously advocated by Dr. Fudd, of Bristol.]

and the same disease—these several kinds of it being only the several expressions of the several degrees of intensity with which the force causative of them operates.

4. That all the phenomena of diarrhœa and cholera are due to hyperæmia, and consequent excessive action of the spinal cord and of the ganglionic or sympathetic nervous system.

5. That all these phenomena are naturally divisible into two classes, as follows:—

*First-Class.*—ACTIVE OR POSITIVE PHENOMENA—DUE TO HYPERÆMIA OF THE SPINAL CORD.

Abnormally copious and pale urine.

Albuminous urine.

Super-abundant secretion of bile.

Super-abundant secretion of pancreatic juice.

Excessive exudation of serous fluid by the serous membranes.

Borborygim.

Excessive activity of the mucous membrane of all the glands of the alimentary canal.

Abnormally high temperature within the rectum.

Excessive activity of the mucous membrane of the gall-ducts and gall-bladder, of the pelves, of the kidneys, and of the female genital organs.

Abdominal gripings.

Excessive expulsive activity of the stomach and bowels.

Simultaneous excessive activity of the thoracic and abdominal muscles.

Sweat in all its grades of copiousness and fluidity.

Disorders of sensibility.

Tremors.

Muscular twitchings.

Fixed stony expression of the face.

Tonic hardness of muscles.

Tightness across the lower part of the chest.

Cramps and convulsions.

Extreme contraction of the urinary bladder.

Restlessness and tossing of the limbs to and fro.

*Second Class.*—PASSIVE OR NEGATIVE PHENOMENA—DUE TO HYPERÆMIA OF THE SYMPATHETIC GANGLIA.

Slight headache.

Deafness of various grades.

Tinnitus aurium.

Dizziness, slight faintness, syncope.

Drowsiness, sleepiness.

Mental states characteristic of diarrhœa and cholera.

Absence of tears, saliva, bile, and urine.

Short, struggling, and rapid respiration.

Cold breath.

Enfeblement of the voice, aphonia.

Oppressive and burning pain at præcordia and left epigastric region.

Algide symptoms: Progressive changes in the visage and in the colour, temperature, and general aspect of the skin.

Loss of cutaneous sensibility.

Serous exudation into the intestines.

Epithelial exfoliation of the intestinal villi.

Enfeblement and death of the voluntary muscles.

Enfeblement and death of the involuntary muscles, cessation of discharges, secretion still continuing.

6. That the different grades of severity with which the foregoing symptoms present themselves in different cases accurately correspond to and express the different grades of hyperæmia of the spinal cord and sympathetic ganglia which obtain in different cases.

7. That as the comparative strength of the cerebro-spinal and of the sympathetic nervous system in relation to each other differs aboriginally in different constitutions, so in cases of diarrhœa and cholera, each of the two groups of morbid phenomena produced by each of those systems will relatively to each other present different degrees of development in different patients. Hence it is that some-

times the copiousness and frequency of the discharges, and sometimes the algide symptoms constitute the predominant features of the malady.

8. That any agent capable of producing general hyperæmia of the spinal cord, and of the sympathetic ganglia, is capable, by doing so, of becoming a cause of both diarrhœa and cholera.

9. That some agents increase the circulation in, and therefore the energy of the whole nervous system simultaneously, and consequently engender diarrhœa and cholera without the operation of any apparent exciting cause. Such agents are solar heat and atmospheric electricity. Hence it is that while diarrhœa and cholera are only epidemic in temperate climates, and, exceptions apart, are only epidemic in such climates during the summer months, they are more or less endemic in tropical climates throughout the year.

10. That though great and continuous solar heat is pre-eminently powerful as a cause of diarrhœa and cholera, even the great potency of solar heat as a cause of these diseases is immensely augmented, if, while the days are hot the nights are cold. Wide ranges of temperature, when the average temperature remains high, cause the amount of blood in the surface of the body to vary extremely within each twenty-four hours, and thus by means of the ebb and flow of the blood-currents, as well as by means of the nervous ramifications throughout the surface of the body, exert an oscillating influence on the circulation within the nervous centres themselves, which rendered permanently hyperæmic by the high average temperature, become still more so in the night, owing partly to the influence of sleep, and partly to the fall of the external temperature, which causes the body to become cool, and the surface arteries, therefore, to become contracted. Careful and exact observations, both in India and in England, have demonstrated that when in connexion with a high temperature there is a great range between the degrees of greatest heat and greatest cold within each twenty-four hours, diarrhœa and cholera are likely to prevail most extensively; and hence it is that in England, as a general rule, September, which is especially notable for its hot days and cold nights, is the month in which those diseases are most prevalent and most fatal.

11. That when a high temperature, with or without great alternations, produces excessive hyperæmia of the nervous centres, the extent of such hyperæmia, and therefore proclivity to diarrhœa or cholera, differs in different persons at the same time, and in the same person at different times, because the constitutional variability of the circulation in the nervous system differs in different persons, and in the same person at different times.

12. That when the spinal cord and sympathetic ganglia have become hyperæmic by the influence of great solar heat, but not sufficiently so to enable them to become self-originate of diarrhœa or cholera, various agents, which, without the co-operation of such hyperæmia of solar origin, would be powerless to produce either of those disorders, are capable, with that co-operation, of becoming exciting causes of both of them.

In India *prolonged marches* of soldiers, *pilgrimages*, and *ordinary travelling on foot*, by bringing into continuous and energetic action the lower segments of the already hyperæmic spinal cord, are notoriously prolific exciting causes of cholera.

*Noxious effluvia* coming in contact with the great expanse of sensory nerve filaments spread over the nasal and pulmonary mucous membranes, excite the already hyperæsthetic brain and spinal cord of persons exposed to great solar heat, to an extent which would not be possible at other times, and thus become exciting causes of both diarrhœa and cholera. "In spite of exceptions," says Dr. Goodeve, "the places in which the air is most vitiated from privies, cesspools, drains, decaying animal and vegetable refuse, or overcrowding and concentration of human evacuations, are those in which cholera has generally been most fatal and most widely spread."

*Impure water*, which in England may be drunk during winter with comparative immunity from bowel complaints, quickly induces diarrhoea and even cholera in summer, when, by the action of solar heat, the nervous system is already predisposed to those diseases. Moreover, impure water taken from the same source all the year round is more impure in summer than in winter, because whereas water at 32° Fahr. dissolves scarcely any organic matter, water at temperatures ranging from 60° to 90° Fahr. dissolves it freely.

*Bad food and eating to excess* are very common exciting causes of cholera in India, where the temperature is always high; generally in temperate climates their morbid influence extends only to the production of diarrhoea; but when, in England, for example, a predisposition to cholera is already established by great heat they very often become the agents of its development.

*Alcoholic fluids* are notoriously stimulants of the nervous system, and, assuming the truth of the doctrines above propounded, my readers will expect that persons who drink these fluids freely in a region where cholera is epidemic, will incur special risks of losing their lives by doing so, and such is the fact. It was found by Dr. Farr\* that, "on Saturday, Monday, Tuesday, and Wednesday, the deaths from cholera were above, and on Thursday, Friday, and Sunday below the average. In the whole country Tuesday was the most, Friday the least fatal day of the week." The remarkable increase of deaths on Tuesday is an instructive consequence of the fact that Monday (*Saint Monday*, as it is called by the working classes) is the day especially devoted to idleness and drinking.

*Dental Irritation*.—Of all exciting causes of cholera or, if the phrase be preferred, of fatal diarrhoea, in temperate climates at least, the process of teething is at once the most extensively operative, the most insidious, and the most deadly. Comparatively few English children are destroyed during each winter by diarrhoea, but the number which it kills every summer is deplorably great, while in those summers which are remarkable for their great heat the number is enormous; and I often marvel how little professional enquiry and reflection are excited by this great infant mortality. How does it come to pass? The answer seems to me easily given: in ordinary English summers solar heat acting alone or even in combination with any of the exciting causes already mentioned, does not suffice to induce cholera or fatal diarrhoea; and in English winters the nervous irritation incident to the process of teething rarely induces diarrhoea, and when it does so the disease is rarely fatal; but when the two exciting forces—solar heat and the nervous irritation caused by teething—are combined, their conjoint force produces that excessive hyperæmia of the already extremely vascular nervous centres of children, which originates the great majority of the very numerous cases called in England "infantile diarrhoea," and in America, where the solar heat is greater, and where, consequently the symptoms of the disease are more pronounced, "cholera infantum."

*Purgative Medicines*.—Besides the several agents already mentioned which easily become transformed into exciting causes of diarrhoea and cholera when heat has already rendered the nervous centres hyperæmic, there are many others which ought to be referred to, but all of which except purgative medicines I must, for the sake of brevity, pass over in silence. That purgative medicines are capable of inducing cholera when the disease is epidemic is proved by an amount of evidence, from the most impartial and authoritative observers, placing the fact wholly beyond question. Testimony to this effect is given by Sir Ranald Martin, Dr. Macpherson, Dr. Laycock, Dr. Mackintosh, Dr. Goodeve, Dr. Twining, Dr. Morehead, and, in short, we find, as Dr. Macpherson says, "the great majority of writers in all countries pronouncing their opinion that when cholera is prevalent it

is not safe to take aperients." The results of the several plans of treatment tabulated by the "Treatment Committee of the Medical Council of the Royal College of Physicians," so as to show the *percentage* of deaths following each plan proved that the *percentage* following the use of eliminants was greatest of all—viz., 71·7, and that the *percentage* of deaths following the treatment by castor oil was even greater than that which followed the use of eliminants in general: it was 77·6 per cent.

(To be continued.)

## CLINICAL LECTURES ON THE DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

### LECTURE XI.

*Inflammation of the Cervix Uteri—Ulceration of—Symptoms of—Treatment of by Depletion, Nitric Acid, and Styptic Colloid—Pelvic Cellulitis—Pelvic Hæmatocele.*

THE great frequency with which inflammatory affections of the unimpregnated uterus occur, resulting as they do in some of the most distressing and intractable ailments to which women are liable, renders the subject of inflammation of the uterus one of great importance. To it I propose to call your attention to-day.

The interior of the uterus is divided into two parts by the os internum, the upper part that of the body, is triangular in shape and is lined by a very thick mucous membrane, which is abundantly supplied with blood vessels and is smooth on the surface. The lower part, commonly designated the cervical canal, is circular, bulging in its centre, and contracted at each extremity. It too is lined with mucous membrane, continuous with that of the body but differing from it in being thinner, and in being arranged in transverse folds, which form the *arbor vite*, the interstices between which conceal numerous mucous follicles and glands. Both these portions may simultaneously be the seat of disease, or one may be attacked independent of the other.

When speaking to you on the subject of menstruation, I pointed out the important part which the mucous membrane lining the cavity of the uterus played in the performance of that function; how easily the discharge which at the catamenial epoch it pours out might be checked, and the ill results to be anticipated from such an occurrence; but in addition to affections following on interrupted or suppressed menstruation, an unhealthy condition of both the body and cervix is likely to occur as the result of abortion, or of imperfect recovery after labour at the full term, when the involution of the uterus being retarded that organ remains in an enlarged and congested condition, one most favourable to the occurrence of inflammation. Other causes too not so clearly traceable produce congestion and inflammation of the cervix, and less frequently of the body of the uterus.

Inflammation of the cervix is never of a very acute character, but the cases we meet with in practice vary greatly in intensity. The more acute form has two well-marked stages, in the one active congestion of the part exists, manifested by great vascularity of the mucous membrane covering the vaginal portion of the organ, which becomes of a bright pink colour, and by engorgement and tumefaction of the substance of the cervix, which however feels soft and elastic to the touch. In the other the mucous membrane being denuded of its epithelial covering, presents the appearance of an irregular abraded surface of a deep red hue which pours out a profuse mucopurulent discharge, and which is studded with numerous papillæ.

\* "Report on the Mortality of Cholera in England." 1848-9.

The os uteri becomes patulous, and its lips everted, while the cervical canal is blocked up by a thick tenacious discharge which is secreted by the cervical glands. This in appearance resembles the white of egg, and is always pathognomonic of endo-cervical inflammation. If you succeed in removing it, and get a glimpse at the membrane lining the interior of the cervix, you will find it also to be of a bright red colour; we seldom however see a case in the very early stage, the symptoms rarely being sufficiently severe to induce the patient to seek medical aid. But generally ere long the inflammation extends to the cervical canal, and then her sufferings being increased she applies for relief.

We have at present in the house a well-marked example of inflammation of the neck of the womb in an early stage, occurring in an unmarried woman. The mucous membrane covering it is smooth, nor does abrasion at any point exist, the os uteri is patulous and a copious transparent, tenacious, discharge issues from the cervical canal, proving that its lining membrane participates in the disease.

Now contrast the appearances presented in this case with those which you saw to exist in the patient occupying the opposite bed. S— B—, æt. thirty-four, has had two children, her illness dates from the birth of the last, two years ago. The cervix is greatly thickened and indurated, its vaginal portion which is of a deep red colour, instead of being smooth and even as in the other, is covered over with little red papillæ which bleed on being touched, while a copious muco-purulent discharge which has to be wiped away before you can see the parts, exudes from its whole surface. The os uteri is very patulous, and is plugged with a mass of tenacious opaque mucus, which when removed after much trouble, discloses a cervical canal, the lining membrane of which is seen to be congested, and covered with large vascular elevations. Here you have an example of the second stage of cervical inflammation, the substance of the cervix is thickened as in the former case; but in addition the mucous membrane is denuded of its epithelium. The surface thus exposed is covered with granular-looking elevations, indeed these have been mistaken for granulations, but they are not new growths at all, but merely the papillæ which abound in this situation, and which have become enlarged and hypertrophied by the existence of the surrounding inflammation, then finally you have a profuse muco-purulent discharge secreted from the diseased surface. The roughened condition of the mucous membrane with its enlarged and prominent papillæ secreting a muco-purulent discharge being a secondary condition the result of the previously existing inflammation.

The case I have just been alluding to affords also an excellent illustration of the condition termed "ulceration" of the cervix, a term the accuracy of which has been warmly disputed. Dr. Bennett defends its use, and on the authority of Petit defines ulceration as "a solution of continuity from which is secreted pus, or a puriform sanious or other matter,"\* but as we usually associate the idea of ulceration with a loss of substance of greater extent than that produced by the mere removal of the epithelium, and I am inclined to agree with the view held by Dr. Farre, that the term ulceration should only be applied to cases in which the loss of substance extends deeper. But if Dr. Farre's definition be strictly adhered to when speaking of affections of the uterus, examples of ulceration of that organ will prove to be very rare. I have never seen as much as one instance of true ulceration of the cervix uteri as defined by him, unconnected with specific disease; indeed I do not believe that such occurs, all this however is a mere dispute about a term, and although I do not think it to be strictly correct, still to avoid confusion, I shall continue to apply the word ulceration to the condition we are considering.†

But cases less severe than the one of which I have been speaking constantly occur, in some there is mere abrasion of the vaginal surface of the cervix, a circle surrounding the os uteri of limited extent, appearing red and abraded, a condition which terminates abruptly just inside the os; or you may have cases intermediate in severity, in which the vaginal portion of the cervix being denuded of its epithelial covering, presents an irregular surface of a deep red colour studded with the hypertrophied papillæ, of which I have already spoken, the cervical canal however not being implicated in the disease, such a surface as that which I have last endeavoured to describe almost invariably secretes a copious purulent discharge. And in addition there is usually a certain amount of vaginitis present. You had an excellent example of this in the case of Mrs. H., the discharge in her was so profuse and weakening that it was for the cure of this that she sought relief.

The milder forms of ulceration of the cervix are not of themselves of any great importance; they seldom give rise to distressing symptoms, nor do they necessarily cause sterility, even when as severe as in the case of Mrs. H., for she became pregnant long before the ulceration was cured; but then the mucous membrane of the vaginal portion of the cervix alone was engaged. It is quite otherwise when that lining the cervical canal is implicated, for then the os becomes patulous, its lips are everted, and a copious, viscid discharge is invariably poured out by the cervical glands; this completely fills up the os, and is seen hanging from it as a rope of thick semi-opaque mucus. This discharge is an effectual bar to conception, and is pathognomonic of cervical disease; whenever you see it, you may at once pronounce that the patient is suffering from inflammation of the mucous membrane lining that canal. Perhaps the best term to apply to this condition is cervical catarrh or endocervicitis. In it the lining membrane being congested is of a deep-red colour, subsequently hypertrophy takes place, and the rugæ become prominent, while its surface is covered with numerous vascular papillæ. When this stage is reached, not only is the os patulous but the cervical canal is relaxed throughout its entire length, as high at least as the os internum.

If you proceed to introduce a sound in a case such as I am describing, you will probably find it to be a matter of considerable difficulty; this difficulty is caused by the point of the instrument becoming entangled first in one and then in another of the folds of the hypertrophied mucous membrane, and it is only after the lapse of some time, and the exercise of much patience, that these difficulties can be overcome, and the cavity of the uterus reached. Some drops of blood are nearly certain to follow the withdrawal the sound, which does not occur when the lining membrane of the cervical canal is in a healthy condition.

In addition to these local symptoms, others of a more general character are invariably present, thus the patient is nearly sure to complain of back ache, and of pain and tenderness on pressure over the ovary, especially on the left side; pain too is frequently complained of along the edge of the false ribs. When this is severe, and particularly if it becomes aggravated at the approach of the catamenial period, I look on it as indicating that the disease has extended up to the os internum. Then irritability of the bladder and often distressing pruritus are frequently present; and, after a time, menstruation is very likely to become profuse and weakening—indeed, not unfrequently it is for the cure of the menorrhagia that we are consulted. This was so in the case of Mrs. B., to whom I alluded when speaking of menorrhagia, and of several others whom from time to time we have had in hospital.

A very instructive case was that of the young married woman, Mrs. —. Her illness commenced soon after marriage; she did not suffer much pain, but latterly had hardly ever been free from a sanguineous discharge; there was also profuse leucorrhœa present. Before coming under my observation she had taken various astringents without benefit. The cause of this was apparent, for on making a

\* "Inflammations of the Uterus," page 82.

† An admirable summary of the arguments for and against the theory of ulceration will be found in Dr. Graily Hewitt's recently published work "On Diseases of Women."

digital examination, the cervix felt as soft as a piece of sponge, and on looking at it through the speculum, it presented an appearance which I can only compare to that of a large raspberry. The slightest touch was followed by copious bleeding. You saw that I brushed over the surface with the saturated solution of perchloride of iron in glycerine; this effectually checked the hæmorrhage for the time, but months elapsed before she was cured. I was inclined to attribute the condition of the cervix in this case, to excessive sexual intercourse in a young woman of delicate constitution.

In the foregoing outline I have endeavoured to trace the progress of a case commencing in inflammatory congestion of the substance of the cervix, in which the mucous membrane, covering its vaginal aspect, participating in the disease, becomes after a time the seat of ulceration, that lining the cervical canal also being implicated in the inflammatory change. This is a very common course for the affection to follow, and an example of it is afforded you in the patient to whose case I have just drawn your attention. It is, however, far from being the invariable one, for without doubt inflammation in many cases first attacks the cervical mucous membrane; ulceration of its vaginal surface follows; the inflammation, and consequent induration, slowly extending into the substance of the cervix.

But we may have cervical catarrh indicating the existence of inflammation of that canal, while the mucous membrane covering the lips of the uterus remains perfectly healthy. When this condition exists we generally find that the case is one of long standing, and that it has crept on slowly and insidiously, the patient dating back the commencement of her illness many years. I shall refer to this condition again by and bye.

Your treatment of cases of inflammation of the cervix uteri must be guided by the stage which the disease has reached, and the form which it has assumed, as well as by the patient's state of health. We seldom see the acute form till the stage of ulceration has been reached. It is too commonly the custom to treat all such cases on one method, namely, by applying nitrate of silver, either solid or in solution, to the surface of the cervix, a treatment in general altogether insufficient, and sometimes positively injurious. Bear in mind that you are dealing with inflammation, or, at least, congestion of the organ, and it is rational that your first step should be to relieve that congestion by local blood-letting. There are two ways of effecting this,—the one by the application of leeches, the other by incising or puncturing the cervix. Leeching is a very troublesome and tedious process, as well as most uncertain in its results: at one time perhaps you cannot get the leeches to take at all, or at most not more than one or two, at another they will bite freely, and perhaps, in spite of all the care you can take, will fasten on the vagina, and profuse bleeding may follow. I have seen the bleeding from this cause so profuse as to compel me to plug the vagina, I therefore now rely altogether on the other method. I practice it very much in the way recommended by Dr. Hall, of Brighton, in the *Lancet* for the 3rd September, 1870. Merely scarifying the surface of the cervix is not sufficient, especially in a case of a very chronic nature and accompanied by induration, I therefore now always puncture the vaginal portion of the cervix tolerably deeply in two or three places. The depth to which I make the point of the knife penetrate varies from  $\frac{1}{8}$  to  $\frac{1}{4}$  of an inch, or even more, according as the cervix be soft and vascular or firm and indurated, for in the former case it bleeds very freely, in the latter it is sometimes difficult to obtain a sufficient quantity of blood. Dr. Hall has had a knife specially made for the purpose by Coxeter, but I invariably use a long straight-backed French bistoury, which terminates in a very sharp point. One great advantage of this plan of treatment consists in the ease and rapidity with which it can be performed. Having exposed the cervix with an ordinary speculum, you make two or three punctures rapidly; this seldom causes pain, if it does it subsides in a few minutes. You can practice this treatment

with equal facility in the wards of the hospital, in the external department, in your own study, or at the houses of your patients.

You have seen how extensively I have carried out this system of local depletion, and how often considerable relief has followed its use. Of course, it is not invariably successful. I have found it to be on the whole productive of quite as much, or even greater benefit in cases of chronic inflammation of the cervix, as in those of a more acute nature.

My rule then in nearly all cases of inflammation of the cervix uteri, no matter what its stage, is first to relieve the congestion by puncturing the part. I only omit this when menorrhagia is present, for when this exists, depletion is in general unnecessary and appears sometimes to be injurious. Your object in that case should be to check at once the weakening discharge. This is best effected by applying freely to the diseased surface a saturated solution of the perchloride of iron in glycerine, which is much less irritating than either the tincture or the liquor, and is generally sufficient if applied freely to check temporarily the bleeding. To apply it you should always expose the cervix with one of Ferguson's glass speculums, and make your applications through it. However, this proceeding is but palliative, and as in all the severe cases the membrane lining the interior of the cervix is implicated in the disease it is essential to dilate its canal throughout its entire extent, so that you may be able to treat every portion of the unhealthy surface. With this intention I introduce one or two lengths of the compressed sea-tangle, taking care that they pass through the os internum, on withdrawing these my usual treatment has been to apply the strong nitric acid freely to the whole interior of the cervical canal, in the manner recommended in a previous lecture. This was the treatment adopted in the case of the woman S. B., of whom we have been speaking. I confined her to bed for three or four days subsequently and then treated the still ulcerated surface by the application of a solution of tannic acid in glycerine of the strength of ten grains to the ounce. I strongly recommend the use of this application in cases of ulceration and inflammation of the cervix, it is especially useful if vaginitis be present. I saturate a pledget of cotton in the glycerine, pouring about half a drachm of it into the palm of my hand and soak it up with the cotton, I repeat this process several times till the cotton is thoroughly saturated, and then attaching a piece of string to facilitate its removal, introduce it up to the os uteri through the speculum and leave it there for twenty-four hours, the patient can withdraw it herself by means of the string. This treatment is often productive of great benefit, the tannin acts as an astringent, while the glycerine produces a copious watery discharge. The result of this combined action is that the surface of the cervix, on the withdrawal of the cotton looks paler and altogether much cleaner and healthier. If much irritation exist in the vagina, I omit the tannin and use the plain glycerine, as it relieves the vaginal congestion more effectually than when it contains an astringent. It was from Dr. Marion Sims's excellent work on "Uterine Surgery" that I learnt the great value of glycerine in the treatment of uterine disease, and I daily appreciate it more. Remember however the glycerine must be very freely used, I commonly employ an ounce for a single application. The quantity which even a small pledget of cotton will absorb is surprisingly large. If the nitric acid be once freely applied to the whole length of the cervical canal, and that you subsequently dress the ulcerated surface with the glycerine of tannin, you will in many instances effect a cure in the course of a few weeks, you had an example of this in the patient alluded to. If the surface be indolent, it may be necessary to apply to it occasionally a solution of nitrite of silver of the strength of from thirty to forty grains to the ounce, also in cases of less severity I sometimes use, instead of the nitric acid, the zinc points introduced into practice by Dr. Braxton Hicks, or if the nitric acid has failed to effect a cure, I introduce them

subsequently; they are often productive of great benefit, specially when no induration exists. They cause however a good deal of pain and considerable local irritation.

But in the case of G. P., one of the patients I am to-day specially directing your attention to, I have adopted a different treatment. In her you may remember there existed great tumefaction of the cervix and extreme vascularity and congestion of the mucous membrane covering its vaginal surface. With the view of relieving this condition I punctured the cervix on three occasions and abstracted a good deal of blood, but although relief from pain always followed this proceeding, very little improvement took place in the condition of the part, I therefore, a fortnight ago, decided on dilating the canal of the cervix, and accordingly introduced into the uterus two pieces of sea-tangle, on removing them I applied, instead of the nitric acid, a solution lately introduced in imitation of the styptic colloid of Dr. W. B. Richardson, it is made by dissolving ten grains of benzoic acid and fifteen grains of tannic acid in four drachms of collodion, to this should be added in the treatment of uterine disease, twenty-five grains of carbolic acid. This is both a mild caustic and a powerful astringent, it forms a coating too over the congested and ulcerated surface, on which I think it exerts a beneficial influence by its contractile power. This preparation is much more suitable for the treatment of cases in which the cervix is soft and spongy than to those in which induration exists. In the present instance it has proved very successful. I am not aware of the styptic colloid having been used in Great Britain in the treatment of ulcerations of the cervix, but a case is recorded in the "Obstetrical Transactions," vol. xi., in which it was used by Dr. Wynne, of Guatemala, with much success.

The milder cases of ulceration of the cervix will generally yield to the use of nitrate of silver; tincture of iodine sometimes seems to agree, but I do not rely on it. I have however noticed that its use seems sometimes to allay the back-ache from which the subjects of uterine diseases suffer so much. I have also used a saturated solution of carbolic acid in glycerine, and have tried it as a substitute for the nitric acid as an application to the interior of the uterus, but it has not realised my expectations.

In concluding my remarks on the treatment of the more acute forms of cervical inflammation especially when, as nearly always is the case, the disease implicates the membrane lining its canal, I must repeat that you have to deal with a most troublesome and often an intractable affection and one which can only be cured by active and energetic treatment.

I stated just now that I had seen that peculiar form of abdominal inflammation known as *pelvic cellulitis* to occur in a patient suffering from inflammation of the cervix uteri. In one case it evidently followed on the application of the tincture of the perchloride of iron, which had been used with the view of checking severe menorrhagia, but in many instances the exciting cause cannot be clearly traced. As we have at present a case of this affection in the house, and as it sometimes occurs in connection with chronic disease of the uterus, I shall take the opportunity of calling your attention to the subject. This patient was admitted in a very anemic condition, having lost a great quantity of blood. She stated that she had aborted three weeks previously, and on examining her it was evident that the hæmorrhage was kept up by the retention of a portion of the placenta. I plugged the vagina and directed her to have thirty drops of the liquor ergotæ and three of the solution of strychnia every third hour. This produced sharp uterine action, and on withdrawing the plug, after the lapse of twelve hours, the placenta was found in the vagina. On removing it the hæmorrhage immediately ceased. Three days subsequently she had a rigor and complained of sharp pain in the region of the uterus; pressure over the abdomen however, caused but little distress. Vomiting soon after set in, and for the next twenty-four hours was incessant; indeed this dis-

ressing symptom did not entirely cease for five days. The pulse, as it always is in these cases, was very quick. On making a vaginal examination immediately after the rigor had occurred nothing could be detected, but the vagina felt hot and she complained of the pressure of the finger causing pain. On repeating the examination after the lapse of twenty-four hours the uterus was found to be immovable, being fixed by a firm hard swelling which extended all round it. This in the posterior *cul de sac* assumed the form of a well-defined tumour which pressed against the rectum. This explained a symptom she had latterly complained of, namely, a constant desire to defæcate; all her attempts however to do so proved useless. Now what has occurred here is, that inflammation has attacked the cellular tissue situated around the uterus and within the folds of the peritoneum, and this has resulted in the rapid effusion of serum.

In this case there are three points worthy of your special attention, namely, the hardness of the swelling as felt through the vagina, the pressure on the rectum which this swelling caused, and the distressing vomiting from which she suffered. The hardness is due to the infiltration of fluid into the cellular tissue surrounding the uterus. This effusion may be circumscribed so as to form a well-defined tumour or be general, as in the present case, its hardness, the rapidity of its formation, and the little pain which pressure causes being its distinctive features. The pressure which this swelling exercises on the rectum often causes much distress, and may by totally obstructing the bowels even prove fatal. Let me impress on you the necessity in such cases of avoiding the exhibition of purgatives. The obstruction is mechanical, and cannot be overcome by exciting the peristaltic action of the bowels. On the contrary, it is your duty to quiet that action by the exhibition of opiates. This was the treatment adopted in the case at present in the house. She took half a grain of opium every third hour, while injections of tepid water were thrown up twice a day into the Rectum, with the view of aiding the descent of any fecal matter which might be impacted in the lower part of the bowel, but the opium had no effect in checking the distressing vomiting I therefore tried the subcutaneous injection of morphia with great success; the injection of one-sixth of a grain always quieted her stomach for two or three hours. Now this is a fact worth bearing in mind. Vomiting frequently follows the subcutaneous injection of morphia, but I have several times seen it check reflex irritation of the stomach depending on uterine disease. Vomiting is a frequent, I was almost going to say invariable, accompaniment of pelvic cellulitis. This I believe is usually due to endometritis, which generally also exists. In the case at present in hospital the treatment adopted, in addition to the subcutaneous injection of morphia, was the keeping the abdomen constantly covered with warm linseed-meal poultices, and the internal exhibition of opium and of hydrocyanic acid. Food could not for several days be retained on the stomach. She had milk and lime-water and milk and soda water in small quantities frequently, and also beef-tea; the latter was also administered as an enema per rectum. She is now slowly recovering.

The tendency of *pelvic cellulitis* is to recovery, it is always a tedious disease, but by carefully sustaining the patient's strength by unstimulating nourishment, and by the avoidance of lowering treatment, such as the exhibition of mercury, purgatives, &c., the patient generally recovers. In the great majority of cases restoration takes place, the swelling being slowly absorbed, but sometimes it terminates in the formation of an abscess which may discharge into the rectum, into the bladder, or open externally. The chief danger consists in the risk which always exists, of the inflammation extending to the peritoneum. A little care will enable you to discriminate between peritonitis and an attack of cellulitis, the pain or pressure is in the latter comparatively trifling, and in the former severe and in it vomiting is an early and prominent symptom, by a vaginal examination always sets

the question at rest, by detecting the existence of a firm hard swelling. The patient at present in the house is suffering from an acute attack, but sometimes the disease creeps on insidiously and its existence may for a long time escape notice, a careful vaginal examination should therefore in all cases be instituted.

There is one affection, of rare occurrence, however with which pelvic cellulitis may be confounded, I allude to those cases in which an effusion of blood takes place into the pelvic cavity, to this affection the term of *pelvic hæmatocele* is applied. The most prominent symptoms of which are the sudden appearance of a tumour in the pelvis, more frequently in one or the other iliac regions, or behind the uterus. This at first is soft, but in time becomes firm and even hard, pain is generally complained of, and there is always a good deal of febrile action present, sometimes there are symptoms of collapse, and generally those of nervous shock. The source from which the blood is discharged is generally obscure, often it is a mere exudation. On some future occasion I shall again refer to this subject, at present I only allude to it, to warn you against confounding the swelling following on the escape of blood with that due to the occurrence of pelvic cellulitis.

#### CASE OF RETENTION OF URINE FROM IMPASSABLE STRICTURE, TREATED BY FILIFORM BOUGIES.\*

By W. F. TEEVAN, B.A., F.R.C.S.,

Surgeon to the West London Hospital; Surgeon to St. Peter's Hospital; late Lecturer on Anatomy at the Westminster Hospital.

ROBERT GREENING, æt. forty-six, cab-driver, residing at 13 North Keppel mews, Keppel street, Russell square, a healthy looking man, came to me for retention of urine, May 7, 1868.

*Past history.*—Was formerly in the army. When twenty-six years old caught a gonorrhœa, which was treated with medicines only by a native doctor in the East Indies. Had gleet on him for ten years. In 1861 (seven years ago), began to notice that he had to urinate oftener than usual, and that he had to strain to expel the last few drops of urine. Gradually got worse, and found that the stream of urine was getting smaller and smaller, so that he could only pass a few drops of urine at a time. Ten months ago, urine began to dribble away from him day and night, so that he was perpetually wet. In April he had to go to the Royal Free Hospital, as he was seized with complete retention. No instrument could be introduced there; was then put into a hot bath, given some medicine, and enough urine passed to give him relief.

On May 4, he came under my care. Considerable fulness in hypogastric region. Man smells very offensively, as all the cloths he has round him are saturated with urine which is continually dribbling away. Much induration in perineum. Penis very congested and eczematous from irritation of urine. Tried for half an hour to pass various kinds of the smallest filiform bougies without success. Could not pass the instrument further than a spot four inches from meatus externus.

On May 6, came to me again, when I again tried in vain for another half hour.

May 8, 4 a.m.—Patient brought to my house with complete retention. Passed no urine since 10 p.m. last night. Weather very warm. Having desired him to stand against the wall, I took the smallest No. 1 filiform bougie, and after one quarter of an hour's trial I succeeded in passing it into the bladder. Left it in for ten minutes, urine began to flow in a very fine stream on its withdrawal. It took one hour nearly to empty the bladder—nearly three quarts of urine came away. The patient standing all the time as he did not feel at all faint. He then went home, rested

and slept well for several hours, and again went out with his cab about mid-day.

May 10.—Passed same instrument and left it in for a quarter of an hour, when I was able to put in No. 2, which I left in for ten minutes.

May 12.—No. 3.

May 14.—No. 4.—The after-treatment of this case was a continuation of gradual dilatations for six months, the patient coming to me every other day. By November 1, I had got him up to 25, after that period he came once a week for the next six months, when I had got him up to 27. From that period to the present, he pays me a visit about once in three months to have an instrument passed. From the date of retention to the present, the patient has never lost an hour's work, the treatment in no way interfering with his occupation.

The *bougie à boule* demonstrated the existence of two long tunnel strictures—one penile the other subpubic. At the present time no stricture can be felt in subpubic region, but there is a distinct ring like stricture in penis admitting 27 French bougie with ease.

This case shows the great value of the French elastic bougies in apparently hopeless cases for its use. The retention facilitated its introduction, and the immediate relief which followed its withdrawal, shows that, for the relief of retention it is not absolutely necessary to pass a catheter, a bougie in this case answering as well. The treatment which was so successful for the removal of the urine, was continued for the cure of the stricture. It is very clear that in this case the bougie entirely obviated any recourse to an operative procedure.

I bring forward this case, to show that we ought patiently to try and relieve the retention with the instrument I found so successful, rather than resort to puncture of the bladder per rectum.

#### CASE OF PROGRESSIVE LOCOMOTOR ATAXY.—DEATH FROM EPILEPSY AFTER THREE YEARS.

By DR. FRANCIS M. LUTHER,  
Cappoquin, Waterford.

ON the 4th August, 1868, I was called to see Mr. Y., who was suffering from a severe attack of English cholera from which he recovered in a day or two, when he called my attention to his eyes. He said he found it impossible for months past to read even large print, and he could scarcely recognise any one. The pupils of his eyes were a little dilated, but not much. He complained also of loss of memory, darting pains in his legs, general debility, and loss of tone and appetite. He acknowledged that he had had syphilis in his youth (he was about fifty-four when he came under my care); had a good deal of trouble of late years, and used to drink freely while leading a sedentary life. I concluded he was getting amaurosis of cerebral origin induced partly by the syphilitic taint and also by chronic alcoholism. I thought the pains in the legs probably rheumatic. I told him he should be temperate or that his brains would get diseased, and I prescribed a blue-pill every night till the gums should be touched. After taking six he complained of loss of power in the rectum and difficulty of locomotion. I added a little opium to the blue-pill. He took one daily for a fortnight without benefit or any effect on the gums. He then consulted a gentleman who examined his retina with the ophthalmoscope, confirmed my diagnosis, and ordered him to persevere in the mercury, till he should be salivated, and to take likewise iodide of potassium with sarsaparilla, and also to blister the crown of his head. He faithfully followed this treatment for six weeks without being salivated in the slightest degree. The amaurosis was not benefited, but his general health became much improved, probably owing to his abstaining from drink. I told him I thought it useless to continue the treatment any longer, and with my concur-

\* Read before the Clinical Society, March 24th, 1871.

rence he went to the Dublin Hospital to consult an eminent specialist who told him that the amaurosis would probably remain stationary, at all events not get worse. Having heard Mr. Y. describe his other symptoms, difficulty of locomotion, loss of memory, electric darts of pain in the calves of his legs, the oculist bade him come again that he might consult with another physician on his case. This he did, and was told to shut his eyes and put his hands over his head. Having done so he nearly fell, and found that unless he looked at the ground he could only stagger as one drunk. He was asked had he spermatorrhœa; he confessed that he had, and was ordered for this latter bromide of potassæ in infusion of hops. He told the oculist of what a quantity of mercury he had taken, but nevertheless was directed to take night and morning a pill containing one-fifteenth of a grain of corrosive sublimate, one grain of valerianate of quinine, and one and a half grain of valerianate of zinc, and also to keep a constant blister over the anterior fontanelle. Neither gentlemen told him the name of his malady, but I guessed that they considered, and indeed that it was, a case of progressive locomotor ataxy. I told Mr. Y. of my conclusion, adding that it was a very intractable disease usually progressing from bad to worse in spite of medical treatment, that the spinal cord was involved as well as a portion of the brain; that nitrate of silver in pills might be tried if the prescription of the Dublin doctors failed to benefit him, but that the true prescription for such cases was "temperance, industry, chastity," as Lindley Murray says. At the time we held the conversation he had been taking the bromide of potassæ and the corrosive sublimate with valerianate of zinc for some weeks with little if any improvement. I ceased my attendance, but was surprised to see by him after some months that his sight was manifestly better, and his carriage very much so. I believe this was brought about by his becoming temperate, but for aught I know he may have been under other medical treatment as well. However, after twelve or eighteen months I fancy he began to drink again.

July 19th, 1871.—I was called to see Mr. Y. this evening. He said "I feel rather uneasy, as during the day my hands begin to twitch every now and then, and at same time I find myself unable to speak. This lasts for some moments, when it passes off. He also complained that for a week previous he saw objects double, not constantly but several times. He said that he had been vomiting very often during the week. I asked had he been drinking? His answer was "not more than usual." How much way that be, enquired I. "Well, from three to five glasses a day," was his answer. I protested that he would kill himself if he did not give up drink. "Strange, how you doctors differ!" said Mr. Y., "Dr. So and so," naming an eminent medical man whom he had consulted about his eyes, "told me I would get *delirium tremens* if I stopped." I greatly doubt the truth of this statement, since Mr. Y. had been temperate for some months when he consulted this gentleman. If it really occurred it was unpardonably indiscreet on the physician's part. I proceeded to tell Mr. Y. that I did not anticipate an attack of *delirium tremens* so much as a fit of apoplexy, and that though I hoped to avert it, yet it would be better to take some necessary steps, such as seeing a clergyman. He expressed great alarm, and agreed to do so. While thus agitated his hands began to tremble, and he began to mumble quite unintelligibly. This passed off in half a minute, and he expressed himself glad that I had witnessed it. I prescribed six grains of calomel and eight grains of scammony, to be taken at once, and a mixture of sal-volatile with tincture of orange and infusion of cascarrilla, to be taken at intervals in lieu of his accustomed stimulants. I forgot to say he complained of numbness of the abdomen and calves of his legs. Next morning I was called to see him in haste, and found him livid, pulseless, bathed in sweat, his eyes turned up, respiration gasping, sibilant, interrupted, unable to move or articulate a syllable. I thought him dying, but dashed some water in his face, and

after a little his breathing got more natural, his colour better, and his pulse perceptible and gradually stronger. He moved his tongue about in his mouth, opened his eyes, gave a look of recognition, after some minutes spake and sat up in bed, looking much as usual. He was not paralysed, nor did he speak thick. In half an hour he got a second fit preceded by convulsive tremor of the hands. From this, too, he rallied. Its epileptic character being manifest, I gave half a drachm of bromide of potassæ. (I should mention that the calomel and scammony given on the previous night had purged him once and that the discharges were dark. He had vomited often during the night.) He shortly threw this up, and got the twitchings in his hands. I applied a tourniquet tightly upon each arm, but it failed to arrest the fit which was of an awful character, asphyxia seeming complete, breathing and pulse becoming arrested for nigh a minute. However, a dash of cold water made him breathe again, and his pulse got strong. Believing the attack would end fatally, I called in another medical man, who recommended 10 grains of calomel to be put on the tongue, and a terebinthinate enema to be administered. This was done but fit after fit came in rapid succession, consciousness no longer returned, and after an hour and a half of insensibility Mr. Y. died quietly. I regret I did not, when I ascertained its epileptic character, upon the second fit threatening, make him inhale chloroform, or give a large dose of chloral between the fits. This epilepsy of the intemperate is, I think, a disease *sui generis*. At least, it differs from ordinary epilepsy in its extraordinary fatality. I would liken it to puerperal convulsions. About six cases which I met all died. None were subject to epilepsy previously, but some were supposed to have had a fit once only before. One would be tempted to perform laryngotomy to prevent asphyxia, but that the intemperate bear operation so ill. It was worthy of note that the progressive locomotor ataxy which Mr. Y. had suffered from three years before should get better and the sight improve. I asked him about this the night before he died. He said he could read pretty well, but that he had lately begun to stagger again. Had my prognosis as to his ataxy when I first attended him been less gloomy perhaps I might have retained some influence over him, and persuaded him to keep temperate permanently. His urine, three years ago, was not albuminous, but I had no time to test it on the last occasion.

#### CASE OF SYPHILITIC IRITIS ATTACKING BOTH EYES IN SUCCESSION, TREATED PRINCIPALLY BY OIL OF TURPENTINE AND BLISTERS.

BY J. SMITH CHARTRES, M.A., M.D. (Univ. Dub.),  
Surgeon 8th Hussars.

PRIVATE J. DE C., 8th Hussars, admitted on the 8th October, 1870, with primary syphilis, viz., an infecting sore, indurated, inflamed, fissured, oval, excavated in centre, discharging thin yellow purulent matter; inguinal glands of both sides enlarged, hard, prominent, those of left groin threatening to suppurate; date of last intercourse, 26th August, 1870; date of first appearance of sore, 7th October, 1870; treated locally; mercury not exhibited in any form; discharged 26th November, 1870 well, sore healed, induration of it, and inguinal glands which had suppurated on both sides, quite gone; fifty days in hospital with primary disease.

Re-admitted on 1st December, 1870, with secondary syphilis, viz., mulberry-looking copper-coloured patches on trunk and thighs, periostitis of thighs and legs, congestion of tonsils, treated by warm baths, Dover's powder at bed time, and eight grain doses of iodide of potassium thrice daily; discharged apparently well on 30th January, 1871, a few skin stains alone remaining, sixty-one days in hospital with secondary disease.

Re-admitted on 4th February, 1871, with well-marked iritis of *left* eye, treated by a solution of atrophine, gr. iv. to  $\frac{3}{4}$ , dropped into the eye occasionally, so as to keep the pupil well dilated; eight grain doses of iodide of potassium thrice daily, combined with (for ten days) three grain doses of quinine; blisters to temple, and behind left ear, but without any benefit up to 23rd February, 1871, on which day being delicate and anæmic, he was put upon drachm doses of oil of turpentine in mucilage thrice daily; on the 27th February, 1871, marked improvement having resulted, half drachm doses thrice daily were substituted until 2nd March, 1871, when all the signs of iritis and conjunctivitis having quickly subsided, the drug was omitted; some periostitis still remaining, five grain doses of iodide of potassium in two doses of infusion of bark were administered thrice daily, under the use of which it soon disappeared.

I was congratulating myself on his speedy cure, when on the 14th March, iritis of *right* eye supervened in an aggravated form, he was ordered a drachm of oil of turpentine in two ounces of mucilage thrice daily. Atropine drops as before, blisters behind right ear.

March 16th.—Eye no better, sick from turpentine, omit it until night, when one dose is to be administered.

March 17th.—Eye in same state, continue medicine thrice daily.

March 18th.—Turpentine again disagreeing, omit it. One grain of opium at bed time.

March 19th.—Eye not improving; half a drachm of oil of turpentine in mucilage thrice to day.

March 20th.—Eye looks somewhat better; blocks of lymph still in iris, pupil irregular; continue atropine drops, half a drachm of oil of turpentine four times a day, blister behind right ear.

March 21st.—One drachm of turpentine thrice daily.

March 22nd.—The first dose yesterday having sickened him, medicine was omitted, to be resumed in half drachm doses four times; or, fifteen minims eight times in twenty-four hours, should the half drachm doses disagree.

March 23rd.—Very sick from turpentine, to have fifteen minims of it four times a day; disguised with yolk of egg and cinnamon.

March 24th.—Continue medicine, twenty drops to each dose.

March 25th.—Continue medicine.

March 26th.—Continue medicine.

March 27th.—Iritis better, some photo-phobia, turpentine to be increased by ten minims up to half drachm doses thrice daily.

March 28th.—Continue medicine, forty minims four times, blister behind right ear, atropine drops.

March 29th.—Forty minims of turpentine thrice daily.

March 30th.—Continue medicine as on yesterday, eye slowly improving, pupil more irregular, lymph being absorbed, intolerance of light, a prominent symptom, conjunctiva red and injected, continue atropine drops.

March 31st.—Not better to day, omit turpentine, which sickens him, to have gr.  $\frac{1}{2}$  of chloride of mercury, and a drachm of tincture of cinchona twice to day, *ex aquâ*.

April 1st.—Omit all medicines, eye better, blister to nape of neck.

April 3rd.—Very much better, a sudden and most marked increase of improvement took place yesterday afternoon at 4 o'clock, which is progressive to day, continue drops, no medicine, had but two doses of the chloride altogether, and no medicine since the evening of 31st ult.

April 6th.—Improving, no medicine.

April 11th.—Eye now almost quite well, but he continues delicate-looking and weak, to take iodide of potassium and quinine mixture, which was resumed on 7th instant.

April 14th.—Eye quite well, recommended for a sick furlough on account of his general delicacy.

April 21st.—Improving generally, eyes quite well  
April 27th.—Discharged to proceed on sick furlough.  
*Summary of treatment, and total amount of each drug administered, viz.:*

*Iodide of Potassium.*—From admission, to 10th March, commenced on day of admission, omitted occasionally and resumed: 585 grains.

*Iodide of Potassium.*—From 11th March, to 27th April, commenced on 7th April, after eye got well: 171 grains.

Total amount of *Iodide of Potassium*: 756 grains.

*Quinine.*—From admission, to 10th March, commenced on 15th February. Omitted occasionally, and resumed. 42 grains.

*Quinine.*—From 11th March, to 25th April, recommenced on 7th April. 114 grains.

Total amount of *Quinine*. 156 grains.

*Turpentine.*—From admission, to 10th March, commenced on 23rd February.  $\frac{3}{4}$  ss.

*Turpentine.*—From 11th March, to 27th April, recommenced on 14th March; omitted occasionally, and resumed.  $\frac{3}{4}$  ss., p.,  $\frac{3}{4}$  ss.

Total amount of *Turpentine*.  $\frac{3}{4}$  ss.,  $\frac{3}{4}$  ss.

*Chloride of Mercury.*—Two doses on 31st March. Gr.  $\frac{1}{2}$ .

*Opium.*—One dose on 17th March. Gr. j.

Number of *Blisters* from admission, to 10th March. 2.

Number of *Blisters* from 11th March, to 27th April. 4.

Total amount of *Blisters*. 6.

Solution of *Atropine*, gr. iv. to  $\frac{3}{4}$ , with which the pupils were kept dilated. A sufficiency.

It may, I think, be fairly concluded from the above case, that syphilitic iritis can be cured without mercury, as the quarter grain of the chloride could have played no part in the process.

How much of the recovery of the *left* eye was due to the 585 grains of the iodide of potassium? and how much to the  $\frac{3}{4}$  ss. of turpentine? it is difficult to determine, the former produced no appreciable result during nineteen days, the latter *apparently* cured the iritis in eight days.

Neither iodide of potassium or turpentine displayed any prophylactic power.

Oil of turpentine persisted in under difficulties, was chiefly instrumented in curing the right eye. Iodide of potassium, with quinine, not having been administered until after it was almost quite well.

It is not easy to account for the fact of the turpentine agreeing with the patient when exhibited for the cure of the *left* eye, and disagreeing with the stomach afterwards so frequently. It is, I think, proved that the drug can be *pushed*, and ought not to be lightly discarded, when the stomach alone suffers somewhat from its use.

It may be affirmed that the blisters were most important items in the treatment of both eyes, but more especially in the case of the right, but it is impossible to isolate their exact share in the cure of the disease. The grain of opium may safely be omitted from our calculations.

The atropine as usual was highly serviceable chiefly as a mechanical agent.

It is satisfactory to reflect that the patient was saved from a combination of mercury poison with the syphilitic poison, to the future integrity, perhaps of his arterial system, as well as general health.

#### Chloral in Tetanus.

M. BENASSON relates a case of traumatic tetanus occurring in a lad thirteen years of age, to whom he was called the third day after the appearance of the symptoms. He found him in a state of almost complete opisthotonos, and determined to try the effects of chloral, and by about the thirty-fifth day the patient had completely recovered. The entire quantity of chloral administered amounted to 180 grammes, commencing with 4 grammes in the twenty-four hours, which almost immediately procured him the sleep he had been so long utterly deprived of. The dose was gradually increased to 8 and 10 grammes in the twenty-four hours.—*Med. and Surg. Reporter.*

### HOSPITALS FOR INFECTIOUS DISEASES.

THE Privy Council has issued a Minute on this subject, tending to show the great mortality caused by the spread of infection, and the measures that should be taken to prevent the rapid spread of infectious diseases. The people are reminded that the Sanitary Act of 1866 makes provision for such cases, by empowering the local authorities to provide the accommodation and Justices of the Peace to order the removal of persons suffering from infectious diseases to hospitals set apart for them. The kind of hospital accommodation required, is treated of separately as regards villages and towns.

A. *Villages.*—“As regards villages, each village ought to have the means of accommodating instantly or at a few hours' notice, say, four cases of infectious disease in at least two separate rooms, without requiring their removal to a distance. A decent four-room or a six-room cottage, at the disposal of the authority, would answer the purpose, or permanent arrangements might be made beforehand with trustworthy cottage-holders not having children, to receive and nurse, in case of need, patients requiring such accommodation. Two small adjacent villages (if under the same nuisance authority) might often be regarded as one. When in a village such provision as this has been made by the authority, and cases of disease in excess of the accommodation occur, the sick must not be crowded together, but temporary further provision must be made for them. The most rapid and the cheapest way of obtaining this further accommodation may often be to hire other neighbouring cottages; or in default of this, tents or huts may be erected upon adjacent ground.”

It may be objected to this plan that such cottages are not usually so well adapted for the purpose as those expressly built for hospitals. But then it should be remembered that small villages cannot expect to be able to afford buildings set apart for such uses. Indeed, the whole scheme is directed towards temporary accommodation, and we are, therefore, inclined to think the Medical Department of the Privy Council has done a wise thing in suggesting so simple and economical a precautionary measure. If the ventilation, lighting, and drainage of such cottages prove inferior to those of hospitals erected for the pu-

pose, it should be remembered that, by acting on these directions, villages may not only prevent the spread of diseases, but may really add vastly to the comfort of those attacked; for it is undeniable that, in default of some such action the sufferers would be left in a much worse condition in their own cottages, and would, moreover, be spreading disease to all those crowded about them. Now, let us turn to the advice offered to larger places. *In towns*, we are reminded

“Hospital accommodation for infectious diseases is wanted more constantly, as well as in larger amount, than in villages; and in towns there is greater probability that room will be wanted at the same time for two or more infectious diseases which ought not to be treated in the same ward. The permanent provision to be made in a town, in order to obtain reasonable security against the spread of infectious diseases, should consist of not less than four rooms, in two separated pairs, each pair to receive the sufferers from one infectious disease, the men and women, of course, separately. The number of permanent beds to be supplied must depend upon various circumstances, chiefly upon the size of the town; but, as no reasonable amount of permanent accommodation could be trusted always to supply the requirements of a place when infectious disease has actually become epidemic, foresight must in the first instance be used, how, in emergency, additional accommodation can be temporarily given to meet requirements in excess of the permanent provision: otherwise, the authorities may unexpectedly find themselves obliged to leave ill-lodged infectious cases at their homes, much as if no hospital had been provided. Accordingly, for a town of any importance, the hospital provision ought to consist of a permanent building, having around it space enough for the erection of temporary structures as occasion may require. Considerations of ultimate economy make it wise to have the permanent building equal to somewhat more than the average necessities of the place, so that recourse to temporary extensions may less often be wanted. In small towns, for instance, if an hospital consisting of four wards and the necessary administrative offices, is to be provided, the original expense of making each ward serve for (say) eight persons will be far less than double that of making the wards for four. And in any case it is well to make the administrative offices somewhat in excess of the wants of the permanent wards; because thus, at little additional first cost, they will be ready to serve, when occasion comes, for the wants of the temporary extensions, and so save great inconvenience and outlay.”

In planning these hospitals several points are insisted on as necessary and with all these we cordially agree. Thus they should be accessible, so as to spare the sick the fatigue and danger that would be incurred by too great distance. They should be located in open spaces. Not less than 2,000 cubic feet of ward space should be ensured for every patient, and 144 square feet of floor space should be allotted to each bed. The temperature should be kept up to 60° F. in the winter. Ventilation should be free. Disinfection should be thoroughly carried out, and cleanliness insisted on in everything. On a sudden emergency huts or in summer tents could be erected on the adjacent ground. The army tents are spoken of as good models. Dryness of site is of the highest importance, and the floors should be raised so that the air can freely pass beneath them.

“In huts, as in permanent buildings for the treatment of infectious diseases, not less than 2,000 feet cubic space, with 144 square feet of floor, should be given to each patient. The ventilation of huts, also, is of equal importance with that of permanent hospital buildings. It is best secured by the combination of side windows with

roof-openings, the latter protected from rain, and running the whole length of the ridge of the roof. The windows, capable of being opened top and bottom, should not be fewer than one to each pair of beds, or in large huts one to each bed, nor should be of less size than the sash window in common use for houses. The ventilating opening beneath the ridge may have flaps, moveable from within the tent by ropes and pulleys, so that the opening to windward can be closed, if necessary, in high winds. Double-walled wood huts may have additional ventilation by the admission of air beneath this outer and inner wall, and its passage into the interior of the hut through openings with moveable covers at the top of the inner lining. The roof should be covered with waterproof felt; the edges of the felt fastened down by strips of wood, not by nails. The hut should be warmed by open fire places, fixed in brick stove-stacks, placed in the centre of the floor, the flue being carried through the roof."

Then comes a consideration of the great trouble that managers will dread. We allude to drainage.

"The sewerage and scavenging arrangements, both of tents and huts, demand very careful consideration. When the tents or huts are placed within the area of a public system of sewerage and water supply, no difficulty will arise; for drains may be laid into the public sewer, and water closets may be easily adapted. But where no system of sewerage exists, the disposal of excremental matters and other refuse will require special provisions. In regard to excrement-disposal under such circumstances, the best method is to adopt the dry-earth system, or, failing this, a pail system, with careful arrangements for the disinfection and subsequent disposal of the excrementitious matter. (See the Departmental Reports, 'On Certain Means of Preventing Excrement Nuisances in Towns and Villages.')

All slops and other refuse should be deposited in metal pails, and removed from the tents and huts at frequent intervals, and so disposed of as not to become a nuisance. Too much attention cannot be given to the careful scavenging of tents and huts, and to the proper disposal of the refuse from them; and the servant or servants to whom the duty is assigned should be under very vigilant supervision."

We think it unquestionable that these instructions will prove useful to local authorities, especially as plans and sections are appended, and we most earnestly hope they will generally be acted upon; for it is certain that prompt action in this way would tend greatly to lessen the mortality from infectious disease—might even stay an epidemic at the outset. Besides this the existence of these hospitals in all directions would be the best mode of promoting the education of the poor in all that relates to the prevention of disease. Every such hospital and possibly still more every such cottage set apart in a village, would act as a centre of education in respect to disinfection, cleanliness, ventilation, over-crowding, and other sanitary matters concerning which the poor are so lamentably ignorant. Every such hospital then tends to promote the civilisation of the masses.

### CHOLERA.

ACCORDING to some, it would appear that cholera is really approaching. Many, however,—especially in London—maintain that we are in no immediate danger of an epidemic. Königsberg has suffered severely, and the disease has extended to Altona, Elbing, and other places. If it should appear about the recent battle-fields, it may assume greater malignancy than it has as yet exhibited. In France, the chief of the health department does not consider it has appeared, but some would attribute the

recent deaths from diarrhoea and cholera to the Indian disease. A morning paper has, in fact, printed an extract from Dr. Decaisne's alarming article in *La France* to this effect:—

"I should very much like to know what it is the official bulletin means by cholera and diarrhoea. What can this diarrhoea be that kills seventy-nine persons in six days? Whatever may be said to the contrary, the choleraic 'situation' is becoming very clearly defined, and for my part I consider as utterly idle any discussion as to a difference between 'cholera nostras,' as it is barbarously called, and Asiatic cholera, and the doctrines of importation and non-importation. I should be very curious to know in what the fatal cases that have been recorded differ from the Indian epidemic. There is no certain remedy against cholera in its last stage, but if taken in time, it is almost always possible to check the disease before it has reached its fatal stage. One of our medical celebrities, Dr. Jules Guérin, was the first to point this out, as long ago as 1832:—'The careful examination of upwards of 600 cases (says Dr. Guérin) has established the fact, that about nine cholera patients out of ten brought to the hospitals had all experienced the symptoms of cholera before being attacked by cholera. Most of them admitted that for four or five days before they had suffered from intestinal derangement, nausea, spontaneous perspiration, and a tendency to fainting. A few had suffered from cramps, pain in the stomach and abdomen, &c., to such a degree that it was impossible not to recognise the symptoms which form the first result of the general cause which culminates in cholera. It is needless to point out the importance of checking the progress of cholera immediately.'"

The report of our own Registrar-General assumes a greater importance, but we question the wisdom of issuing in such form some of the recommendations that appear. The Post-office experience of sulphuric acid has previously been made widely known, and in the opinion of many need not have been put so prominently forward. How will every one accept the dictum that the epidemic is sure to reach us?

We append a few extracts from the official document.

Asiatic cholera has made further advances; Dr. Zuelzer reports that it is now at Elbing and at Dantzic. In Königsberg from fifty to sixty cases occur daily, forty-five to fifty per cent. of which prove fatal. Four cases with three deaths are reported in Berlin.

In London 2,103 births and 1,682 deaths were registered last week. After making due allowance for increase of population, the births were fifty-seven below, and the deaths 218 above the average numbers in the corresponding week of the last ten years.

The 1,682 deaths in London, included 82 from small-pox, 20 from measles, 24 from scarlet fever, 6 from diphtheria, 25 from whooping-cough, 22 from different forms of fever (of which 4 were certified as typhus, 11 as enteric or typhoid, and 7 as simple continued fever), and 487 from diarrhoea; thus to the seven principal diseases of the zymotic class 666 deaths were referred last week, against 525 and 610 in the two preceding weeks.

The mean temperature last week, although showing a decline upon the previous week, exceeded the average on each day of the week.

The deaths referred to cholera and choleraic diarrhoea in London declined from 40 in the previous week to 28 last week. All who died were children, mostly infants.

The fatal cases of small-pox in London, which had been 87, 96, and 80 in the three previous weeks, were 82 last week.

The cholera epidemic now in Prussia will probably in its destined season enter England, as it has hitherto done, in spite of quarantine.

It is now known that where a place is clean, where the

waters are pure, where the people are not crowded, where good administrative arrangements are made for the early treatment of attacks in the first stage of diarrhoea, the epidemic is disarmed of nearly all its terrors.

But as English towns are still dirty, are dotted over with cesspools or fouled by bad drains, and the waters alike of wells and of rivers from which towns draw their supplies are soiled to some extent by sewage, we can at present expect no absolute immunity. Commissions and committees have left our water supply much as it was; the hard waters of the rivers are not purified by Clark's process, nor are the pure unpolluted streams brought uncontaminated down to the cities in the plains.

Still, much may be done, if cholera pursue its customary course, by commencing at once all useful works of purification, so as to mitigate its virulence when it attains its highest development next year. To the able engineers of the water companies we must trust for much valuable assistance.

Town councils and local boards should organise their medical staff at once, in order to carry out a proper system of relief in conformity with the principles prescribed by the Local Government Board.

Some of the cholera cases in London are severe, but they are not of the Asiatic type. They demand the same kind of precautions. The thing to bear in mind is, that diarrhoea prevails; that unless this diarrhoea is cured—as it can be near its origin—it turns in a certain number of cases into cholera, over which medicine exercises less control. The serum escapes with great velocity, and when once out it is as difficult to replace as the blood from a bleeding wound.

Why did 487 persons, chiefly children, die of diarrhoea, twenty-eight of simple cholera last week, and why will, probably, as many die of the same disease next week? Chiefly because the cases are not treated in their early stages.

Not only the ignorant, but educated people neglect due precautions: the inconvenience is so slight until it is too late.

#### SENSATIONAL STATISTICAL SANITATION.

THE British Medical Association mourning over the sanitary destitution of the poor Irish savages, detached at its Plymouth meeting one of its members—Mr. Benson Baker—that he might illumine the benighted world across the Channel with the benignant rays of the all-benevolent Association. Mr. Benson Baker's function would, of course, be a nullity unless he established an epidemic of sanitary horror by which to work himself into a little notoriety, so a couple of days after his arrival, before he had time to rub his eyes after the journey, he writes to the Dublin papers a violent attack on the Sanitation of Dublin, and on the Public Health Committee of the Corporation. He says that "no one passing through the streets can fail not only to see, but to be informed by another sense that excreta and decomposing refuse are producing *excrement reeking air*. Thirteen thousand of the citizens of Dublin suffer from fever annually, and in a period of twenty-five years every citizen of Dublin will have had fever; that is, the gross total of fever will equal the population."

The first sentence of this sensation statement is simply and absolutely untrue—a preposterous hyperbole, which nothing could prompt but the necessity for getting up sanitary steam to hoist Mr. Benson Baker and the unappreciated British Medical Association. Dublin is muddy as to its thoroughfares, and no cleaner in its purlier than other large cities; but it is an outrageous misrepresentation to talk of its "excrement reeking air." As far as

anyone can judge, by sight or smell, its streets are neither better nor worse than similar streets elsewhere.

We are, however, relieved of the necessity of dealing further with Mr. Benson Baker's statements, for they have been completely and curtly disposed of by Dr. Mapother, the Dublin Health Medical Officer of the City. He shows that Mr. Benson Baker has credited the City of Dublin with the fever of all Ireland, and made other errors in figures of such gravity as totally to discredit him if his exaggeration failed to do so.

*The British Medical Journal*, while it repeats in its last issue these untrue and libellous statements, administers a cutting rebuke to its *harum scarum* delegate. It says: "Mr. Baker's statistical observations are *not* without flaw, but his strictures are *well-intended*, and they are *likely* to be found based upon facts, and worth serious consideration."

The fact briefly stated is, that the street scavenging of Dublin is abominable, but the Public Health Committee has done and is doing its very best for the sanitation of the city and the Corporation, and the ratepayers are being educated up to sanitary reform as quickly as can be expected.

## SCOTLAND.

### EDINBURGH.

CRAIG v. BLAKE.—It is stated that of the nine hundred pounds to which Miss Jex Blake costs in the action of Craig v. Blake amounted eight hundred pounds are already subscribed.

LADY MEDICAL STUDENTS.—According to recently-published statistics of the University of Edinburgh Botanical Class, in the session of 1871 the number of pupils was 306. Of these, 241 (including 5 ladies) were medical students, 12 pharmaceutical students and 53 general students.

### THERAPEUTIC ACTIONS AND USES OF TURPENTINE.

At the last meeting of the Edinburgh Medico-Chirurgical Society—Dr. H. Bennett in the chair—Dr. Warburton Begbie read a paper on the above subject. He gave a brief sketch of the ancient history of the drug from the time of Hippocrates, with a notice of the various forms in which the oleo-resins of the coniferæ are used or have been used in therapeutics. Oil of turpentine was described as being irritant and stimulant, quickening the circulation and augmenting the temperature of the body. In larger doses it produces a sort of intoxication; in drachm doses it is hypnotic. Externally it is a valuable rubefacient, and is absorbed by the skin so as very soon to be recognised in the breath, and by its characteristic violaceous odour in the urine. The production of this violaceous odour in its perfection seems to be a test of the integrity of the urinary organs, as it is less marked or absent in disease of the kidneys. The therapeutic actions and uses of turpentine are various. 1. As a cathartic it is uncertain, but along with castor oil it is useful in cases of obstinate obstruction and tympanitis. 2. As an anthelmintic it is chiefly used as a cure for tapeworm; also, in the form of enema it destroys ascariæ and lumbrici. 3. Though turpentine sometimes causes hæmaturia, it cures certain passive hæmorrhages. It is useful in purpura, probably acting through the nervous system; and is useful also in hæmoptysis, hæmaturia, and uterine hæmorrhages. 4. As a stimulant, it is especially valuable in adynamic fevers; as in the stupor

of typhus, in certain kinds of delirium, and in the later stages of enteric fever with a dry tongue. 5. In certain nervous diseases, such as epilepsy and chorea, it is said to be very useful; but in epilepsy it is supplanted by bromide of potassium, and in chorea by arsenic. In certain forms of sciatica and crural or brachial neuralgia in the aged, twenty minim doses thrice daily have a very good effect. In the nervous headache of delicate females, and the headache which is induced by fatigue, it is a better stimulant even than strong tea, and without the effect which tea so often has of banishing sleep. 6. In all chronic discharges from mucous membranes, such as chronic and fœtid bronchitis, it is very useful, and even is advantageous in gangrene of the lung in checking the fœtor. Under this head some interesting cases were given of gangrene of lung depending on the presence of foreign bodies.—A discussion followed, in which the Chairman, Mr. B. Bell, Dr. T. R. Fraser, Mr. Lister, Dr. Smart, Dr. T. G. Stewart, and Dr. Joseph Bell took part. Additional evidence as to the value of turpentine in hæmorrhage and in chronic mucous discharges was elicited.

## Notes on Current Topics.

### Vaccination Law in the House of Peers.

If the House of Lords were placed on its trial as to its *raison d'être*, no more cogent instance of its value as a check on impulsive legislation could be adduced than is afforded by its action in reference to the new Vaccination Act. Yielding weakly to the unreasoning clamour of the mob, the Government consented to the appointment of a Commission to enquire into the necessity and efficacy of compulsory vaccination. To do so was a fatal mistake, a step for which the Government well knew that there was no reason whatever, and which it conceded simply for the purpose of conciliating the clamorous democracy which Mr. Gladstone avows it is his cue to cultivate. By granting an enquiry into facts respecting which we solemnly declare that no thinking man who took the trouble to inform his mind could have the slightest doubt, the Government shook that public confidence which it has been the whole aim of vaccination legislation to establish, and left it open to general suspicion that there might really be something more in the anti-vaccination outcry than the doctors admitted.

The doubt thus thrown upon vaccination it will take years to efface, and those who know nothing of the subject will naturally conceive that if there be so much to be said against the practice, it may be safely put off, if not abandoned altogether. We repeat, then, that the Government conceded the enquiry in the full conviction that there was nothing to enquire into, but simply to satisfy the dupes of the professional agitators, who had taken this road to notoriety.

The Commission sat, and the result was, as might have been expected. The evidence, *pro* and *con*., was in the proportion of infinity to nothing; indeed, no evidence against vaccination was produced, but many of the vaccinophobiacs declared that however they might be "persuaded against their will, they'd be of the same opinion still;" and, as a matter of course, the representatives of that view dissented from the report of the Commission, just as they would have done if the investigation had occupied a century, and if it had been possible for the evidence against them to be more conclusive.

But the inevitable "working man," the political *arbitrè* *elegantium* of all matters scientific or social, had to be satisfied, so the Commission resolved to the effect that though small-pox was a disgusting and dangerous disease, and though persons who refused to vaccinate their children were guilty of propagating it, yet, nevertheless, any fanatic twice convicted and thereby proved beyond doubt to be dangerous to society, should thenceforth be allowed to continue the dissemination of the disease to all time.

This, however paradoxical it may appear in all practical respects, was the advice of the Commission, and the Government accordingly made it part of their Bill that no person should be prosecuted oftener than twice for refusing to vaccinate.

The House of Lords, untrammelled by the terror of the "working man," and under no political compulsion to keep professional stump-orators in humour, have rejected this ridiculous proviso, and compulsory vaccination thus happily escapes emasculation.

The Government and the Commission admit that the scourge of small-pox is such as to justify interference with the liberty of the subject, and they admit also that to refuse vaccination is to propagate small-pox. Why in the name of common sense, should a wrong-doer be absolved from punishment because he has been guilty, not once, but several times?

### Use of Methylated Spirit for Tinctures.

THE fraudulent use of methylated spirit in medicine has been repeatedly exposed in this Journal, and has become in Irish Poor-law pharmacy so much a matter of course, that it now hardly attracts attention. The Commissioners of Inland Revenue, in their last Report, notices that during the past year eight samples of medicines for internal use were found to have been prepared from methylated spirit. They comprised sweet spirits of nitre, paregoric, and the tinctures of catechu, rhubarb, and cardamoms.

### Substitutions for Anti-Scorbutics for Shipping Purposes.

DURING the last year 635 samples of lime and lemon-juice, and 100 samples of spirits for fortifying the same, have been examined by the Inland Revenue Commissioners. Eighty of the former, and seven of the latter, were recommended for rejection.

### Adulteration in the Custom-House.

OF tobacco 152 samples have been examined by the Custom-House Commissioners; 28 contained adulterants such as sugar, liquorice, and logwood. In one case the sample was adulterated with 30 per cent. of liquorice. The amount of tobacco cleared for consumption during the year 1869 gave an average of 1 lb 5 $\frac{3}{4}$  oz. per head of the population, against 13 $\frac{3}{4}$  oz. in 1841. Adulterated samples of snuff have been found to contain oxide of iron, alumina, glass, coal, pinewood, fustic, straw, and an excessive amount of sand.

Sixty-three samples of coffee have been examined during the year, of which thirty-two were genuine; thirty were adulterated with roasted locust beans to an extent varying from 10 to 30 per cent., and one with a vegetable substance that could not be identified.

### The Vaccination Amendment Act.

THE Act which received the Royal Assent on the 21st ult., and which is to come into operation on the 1st of January, 1872, makes some important changes for the more effectual carrying out of vaccination in this country. In the first place, it is rendered compulsory upon guardians to appoint one or more persons as vaccination officers, whose duty it shall be to prosecute persons charged with offences against the act, or otherwise to enforce its provisions. The Local Government Board are to have equal powers in matters relating to the officers as they have with regard to other officers in matters relating to the relief of the poor. The vaccination officer is to perform all the duties imposed by the original act on the registrar of births and deaths, except as to the duty of giving notices, but all the fees received by such vaccination officer are to be accounted for to the guardians. Public vaccinators are to be compelled to give a certificate in the case of every child unfit for, or insusceptible of, successful vaccination to the vaccination officer, and deliver to the parent of such child a duplicate, and every certificate of successful vaccination is to be transmitted within seven days after it is ascertained that the operation has been successfully performed to the vaccination officer and parent of the child, and a penalty not exceeding 20s. may be inflicted on every person who prevents a public vaccinator from taking from any child lymph, as provided by the 17th section of the principal act. When any parent of a child fails to produce any child for vaccination when summoned, such parent shall also be liable to a penalty of 20s., and also for not transmitting a certificate of vaccination to the officer. Registrars of births and deaths are to transmit once a month to the vaccination officer a return of all births and all deaths of infants under twelve months, and for which the registrar is entitled to receive a fee of twopence for every birth and death included in that return, to be paid to him by the guardians of the parish in which his district lies. Persons who undergo the operation of re-vaccination by a public vaccinator can claim to have it performed without charge, and in cases where persons are re-vaccinated in houses where others may be sick of small-pox, the vaccinator can claim to be paid for his services by the guardians. In all matters relating to vaccination the Local Governments Board is substituted for the Poor-law Board and Privy Council.

### The Cholera.

THE Berlin Correspondent of the *Times*, under date of August 23, reports that the central and north-western portions of Russia continue to be ravaged by cholera. Moscow, Vladimir, and Suwalki—the latter bordering on East Prussia has spread the disease to German territory—are at present the districts most severely visited by the plague. Poland proper is as yet exempt. Reliable statistics as to the number of cases are wanting, but the vast extent of its area, together with what we hear, leads to the conclusion that the disease this time is not to be made light of. In Prussia, Königsberg, remains the hotbed of the epidemic. In the seven days ending the 18th, that city had 130 deaths by cholera, among which were fifty-one children below the age of fourteen. The preceding week but one-third this number had succumbed to the scourge. Since the last returns were published there seems to have

been an improvement. As a precautionary measure the police authorities throughout Prussia have been directed by the Home Office to pay the strictest attention to the state of the sewers and cesspools, which have to be daily disinfected and deodorised, and frequently emptied. It will be an Herculean task to cleanse the Augean stables of Berlin. Perhaps the Town Council, who have been so long wavering as to which system to choose, will now at last realise the necessity of selecting one among the various modern methods of drainage. The antiquated cesspools and sewers we have are simply an abomination. The sale of unripe or rotten fruit is prohibited.

### Hampstead Small-pox Hospital.

A LITTLE while ago we reported a case of mistaken identity which was contradicted "by authority." We did not wish to enter into controversy on the subject and said no more. But as usual we were right. The case was not "impossible" our opponents alleged. We now have "by authority" the confession that a child has been lost. We do not propose to supersede the action of the Asylums Board in the enquiry, that must be made into the allegations respecting the Hampstead Asylum. Some contemporaries have pronounced an opinion before the case was in court. We hope they will not be too hasty in contradicting us, as they may if they persist in this plan, have to contradict themselves more frequently than ever.

### A New Mode for Cleansing Closet Pans.

MESSRS. HARRISON & SONS, of 26 Change alley, London, have forwarded us an appliance, designed to close the aperture in the pans of water-closets for their more effectual cleansing. The insertion of the plug preventing the escape of the water until the pan is filled, on its removal, the water rushes down, carrying with it any foul matter which may have accumulated on the pan.

The plug, which consists of a band of India rubber around a block of wood, with a handle in the centre, can be made by any turner, the inventors liberally offering patterns to medical men, sanitary inspectors, and others.

It will be found serviceable in places where only a limited supply of water is obtainable; but like a great many new inventions so-called is not in our opinion any improvement upon the existing mode of cleansing pans by a good stiff brush.

### Coma from fifteen grains Chloral Hydrate.

DR. SHAW, in the *Philadelphia Medical and Surgical Reporter*, describes the effect of a fifteen-grain dose of this substance, given to a paralytic patient for severe abdominal pain. The man soon lapsed into deep coma, with spasmodic and occasionally suspended respiration, which continued eight hours, during which time his life was despaired of. He then recovered.

### The Physiological Action of the Codeia Derivatives.

DR. MICHAEL FOSTER has investigated the physiological properties of the derivatives of codeia, as we have given an account of their chemical properties as stated in Professor Wright's paper, we complete the subject by noting some of Dr. Foster's experiments.

The hydrochlorate of chlorotetracodeia, and the hydrobromate of bromotetramorphia, in doses of a decigramme by subcutaneous injection or by the mouth, produced in adult cats in a very few minutes a condition of great excitement, almost amounting to delirium, accompanied by a copious flow of saliva and great dilatation of the pupils. Micturition and defecation occurred in some instances, and vomiting was observed on two occasions with the morphia-salt, but was very slight. The excitement was very peculiar, being apparently due partly to increased sensitiveness to noises, and partly to an impulse to rush about.

The same doses of the morphia-salt given to a young kitten produced the same flow of saliva, dilatation of pupils, and excitement (without vomiting); but the stage of excitement, which in adult cats passed gradually off in a few hours, was followed by a condition marked by a want of co-ordination of muscular movements, and presenting the most grotesque resemblance to certain stages of alcoholic intoxication. This stage was followed in turn by sleepiness and stupor, in which the kitten was left at night; in the morning it was found dead.

Two observations have shown these salts paralyse (in dogs and cats) the inhibitory fibres of the pneumogastric; they also seem to lower the internal tension, but want of material has prevented from ascertaining how this is brought about.

On *rabbits* neither salt, even in doses of a decigramme, seems to have any effect, except perhaps a slight excitement. There is no dilatation of the pupils, no flow of saliva, and, if one observation can be trusted, no paralysis of the inhibitory fibres of the pneumogastric.

No marked difference was observable between the two salts, except that the morphia salts seemed rather more potent than the corresponding codeia bodies.

The salts of deoxycodeia and deoxymorphia given by mouth or by subcutaneous injection, in doses of a decigramme, produced in adult cats, almost immediately after exhibition, a series of convulsions much more epileptic in character than tetanic. In one case there was a distinct rotatory movement.

In a few minutes these convulsions passed away, leaving the animal exhausted and frightened. Then followed a state of excitement with dilated pupils and flow of saliva, very similar to the effects of the tetracodeia and tetramorphia salts, but less marked.

### The Medical Staff of the Camp.

THE corps taking part in the Autumn manoeuvres which commence on Saturday next will be under the medical charge of Inspector-General R. Lawson, Staff-Surgeons Major H. Kendall, M.D., — Sinclair, M.D., and J. J. Clifford, and Staff Assistant-Surgeon Martin.

### Safety from Drowning.

THE importance of teaching the young of both sexes to swim cannot be over estimated. In many Continental States the art is a necessary and almost compulsory part of education, yet we, who have a continuous sea-board, and to whom our mercantile and other pursuits naturally give more of an aquatic character than other nations, so far neglect this simple yet invaluable accomplishment as to make its possessor appear almost a *rara avis*. Any one who is in the habit of visiting the sea-side will readily

perceive that not more than one in every hundred bathers can boast of this acquirement.

Until this inexplicable state of things, which is daily becoming a greater reproach to us, be removed by a clause in our educational code, it is well to look for some mode of saving the lives of the untutored and to enforce upon the owners of bathing machines the necessity of keeping some handy life-belt or buoy ready for instant use by any person who may be nearest to the scene of accident. The most simple and, at the same time, the most effective appliance we have yet seen is a waterproof belt which opens and closes in the quickest and most simple way imaginable. When closed it occupies a very small space, but by giving one turn to a brass screw at the end the air instantly rushes in and inflates the belt to a length sufficient to encircle the body. The lifting power of this belt in the water is about 16 lbs., and as 5 lbs. will keep a man of 12 stone from sinking, any one swimming out with one of these, or if thrown out to drowning persons, would save three from a watery grave. The writer can speak from experience of this appliance. Being a good swimmer he has tested it in various ways: in one instance he swam into deep water with three others—non-swimmers—all of whom were supported by it with their heads above water for some minutes, and then without difficulty pushed themselves to shore. We believe the invention is by Count de Liancourt, and certainly when daily reports reach us of innumerable deaths while bathing it does seem extraordinary that some such appliance which costs but a few shillings is not found in every spot where bathers congregate.

### London Water.

IT appears that Clark's process for softening water has been represented in official quarters as very effectual. It is mentioned this week in the Registrar-General's returns from which we learn that the following valuable facts have been communicated by Mr. Robert Rawlinson, C.B., C.E.

"The average daily water supply to the metropolis was 111,292,104 gallons in June, and 112,107,697 gallons in July. Now in each million gallons of these waters there is about one ton of bicarbonate of lime, or 111½ tons in June, and 112 in July. About two-thirds of this weight of lime or chalk would be removed by Dr. Clark's softening process; that is, in June 74 tons, and in July about 75 tons. In each year about 25,000 tons of useless lime would be removed from the Metropolitan waters by the simple and easy process now in use at Canterbury."

The riddance of the foreign matter which deprives water of some of its cleansing properties is in itself an advantage; but besides this, the fine precipitate of chalk carries down with it suspended impurities and probably frees it from choleraic and other contagious. It is a most effective filtration.

### Mammary Abscess and its Remedy.

DR. JOSEPH R. BECK, of Lancaster, Ohio, states in the *Philadelphia Medical Times*, his mode of effectually preventing any abscess of the mammary gland from troubling either the patient or the obstetrician. Whenever symptoms of inflammation of the gland arise, every effort should be made to arrest the secretion of milk; this will relieve the mother, and not necessarily interfere with the well-being of the child.

As soon as there are any symptoms that mammary abscess is likely to occur, he orders alcoholic extract of belladonna, four drachms; glycerine, a sufficient quantity to mix them to the consistence of a moderately thin paste. This is to be spread in a medium thick layer with a spatula, over and upon both mammary glands, from the sternum to the axilla. Cover with a cloth dipped in olive oil, and this in turn with oiled silk. Allow the dressing to remain undisturbed during a variable period of from two to three or four weeks, inasmuch as it can be worn by the patient for any length of time without inconvenience.

The argument in the case is directed, of course, to threatening abscesses: but all will at once recognise the appropriateness of the treatment in cases of still-born children, where it is certainly desirable to arrest the secretion of the milk at once. In these cases apply the remedy within an hour or two after the birth of the child. Dr. Beck never knew this treatment to fail of its desired effects, where it was used in time.

### Electricity in Sickness of Pregnancy.

DR. S. IFFLA lately read before the Medical Association of Victoria, "Some Observations on the Use of Electricity in Medicine," which are printed in full in the *Australian Medical Gazette*. He directed attention to the use of this agent in the sickness of pregnancy, and assured the Society in those intractable cases of sickness and vomiting during pregnancy, where no food can be retained in the stomach, he had found it succeed when everything else had failed. He related one of his most remarkable cases. Nothing afforded the patient the slightest relief; she was wasted to a mere skeleton. Dr. Iffla says he never beheld a living object so ghastly; her face was of a livid hue, the surface of her body was bedewed with a cold moisture; she had not retained a particle of food for many days. He transmitted a steady current of electricity through the epigastric region; relief was prompt, the patient rallied, and was soon able to retain a small quantity of bland aliment. After a few more applications the sickness entirely ceased, and did not return. About three months afterwards she was safely delivered of a healthy child. In a later pregnancy of this patient the same treatment was adopted with success.

### Chloral Hydrate in Large Doses.

DR. J. G. ROGERS, of Madison, Ind., writes in the *American Practitioner* for August, "Observing in the June number of the *American Practitioner* some considerations on the maximum dose of chloral, in which it is concluded that one hundred and twenty grains is probably as much as the vital powers will bear at one time, I am induced to state that in a case of *mania à potu* in an adult man I have given *one ounce* in six doses, *all within one hour*. It is a well-established law that *effect, and not weight or measure*, should limit or fix the dose of any medicine. In the case referred to I proposed to quiet the patient *tuto, cito et jucunde*. To do this one ounce of chloral and an hour's time was required. The patient slept naturally, to all appearance, during three hours, and awoke well but weak, with no nausea, and only a slight headache. Next day he went to his work. The preparation used was of the usual strength. In a case of terrible headache, recurring weekly, in which morphia or chloral could not be satisfactorily used, I gave the lady *one ounce* of bromide

of potassium in two doses within an hour. The non-effect of the first half justified the second dose. The headache ceased in fifteen minutes after, and she slept naturally for four days and nights. This rather extraordinary slumber, however, was easily interrupted, and the patient took her meals regularly and went to sleep again. During these short wakings the mind was rational but slow. No functions were interrupted or changed, but the appetite, which before was poor, was much improved. The effect wore off gradually on the fourth day. Since then the attacks have yielded to smaller doses."

DR. DALRYMPLE, M.P., of Bath, has gone on a visit to the United States for the purpose of collecting evidence as to the treatment of habitual drunkards.

DR. KIRK writes to Sir R. Murchison that he has no further account of Dr. Livingstone. Latest information leads him to suppose that the traveller is moving slowly but safely.

By the lamented death of Dr. Hyde Salter, the senior physician to Charing cross Hospital, and the lectureship "On the Principles and Practice of Medicine" to the school attached to that hospital have become vacant.

THE vacancy created in the staff of the Middlesex Hospital, by the election of Dr. Murchison at St. Thomas's, has been filled by the appointment of Dr. Headlam Greenhow.

THE will of the late Mr. Loder has just been proved under £40,000 personalty. The Salisbury General Infirmary receives the magnificent bequest of £5,000 therefrom.

THE mortality in Paris during the week ending the 2nd of September was 846; 35 persons died from dysentery, 91 from diarrhoea, 36 from cholera, and 4 from cholera.

A FIRE broke out in the laundry of the Portsmouth and Gosport Hospital on Thursday, which at one time threatened the destruction of the whole building, but owing to the promptitude of the troops and the authorities this calamity was fortunately averted. The wards of the hospital were full of inmates.

THE "Medical Register and Directory of the United States" will shortly be issued by Dr. J. M. Toner, of Washington, and will include the names of 50,000 physicians. It will, moreover, contain statistics relating to all the medical schools, hospitals, medical societies and institutions of the country, and will, in this way, embrace information of value to medical men.

## SPECIAL CORRESPONDENCE.

PARIS AND THE RHINE IN 1871.

[LETTERS FROM DR. CHARLES R. DRYSDALE.]

To the London Editor of the MEDICAL PRESS.

August 10, 1871.

ON approaching the frontiers of France, I found the station-master of Appenweier (Baden), like many of us in

London, entirely opposed, although a German, to the holding of Alsace and Lorraine by the Germans. Living quite on the frontier, he was convinced that the Alsacians and others would not submit to leave France. The noise of the bombardment of Strasbourg was heard well at this station, ten miles off. On reaching Kehl, the devastation caused by war became everywhere visible. In a walk from Kehl to Strasbourg, the Rhine railway bridge was seen to be, on the German side, composed of wood. The miseries sustained by Strasbourg you know well. A lady told me that 800 persons were killed during the siege. The houses shattered seemed endless. German soldiers everywhere, and business broken up; dissatisfaction on most faces. Such are the impressions of a visit to Strasbourg. Every man I spoke to breathed revenge; only the women seemed to have had enough of starvation and sorrow.

The German soldiers, too, are terribly tired of remaining away from home so long; and not a few, when they found I was not a Frenchman, cursed their Emperor as a Spitzbube, a word which, I suppose, may be translated as a rascal. The poor French soldiers I spoke with in Alsace and Lorraine had most of them been prisoners in Germany, and still burned for *la revanche*. What a strange thing it is, that two such able nations cannot learn to give up such painful thoughts, and take to fighting nature instead of each other.

Excellent as are the Prussians, and much to be admired in many ways for their learning, abilities, and universal education, there is something most truly fascinating in French manners, which strikes one on leaving Germany and suddenly entering France. Both of these nations have much to learn of one another. The French have to adopt, as ourselves, obligatory education, and the Prussian military system; but, again, the Germans have even more valuable lessons, perhaps, to learn from their enemies, *i.e.*, how to diminish indigence, and make social life more agreeable and artistic. There is a *brusquerie* in Prussian manners, which is a little repulsive sometimes until the stranger becomes well acquainted, which is rare, indeed, in polished France.

There are German troops, fair-haired, good-natured looking boys most of them now-a-days, posted all along the line, at every station from Strasbourg to Pantin, near Paris. Most of them look rather dirty, and too fond of tobacco, but in good health, although terribly in want of amusement and their usual beverage, beer. The French mutter curses upon them at all of the stations, and express the eager wish to destroy the poor young men, who, on their side, desire nothing better than to be away out of the country; and, some express the hope, shared by most of the German soldiers I spoke with, that the new empire of Germany may soon break up and end in a Republic, which shall restore to France her provinces, and live in *liberté égalité*, and *fraternité* with her. Such are the dreams of good and true men; but the fiercer sort of soldiers and citizens swear to be avenged, and to carry war into Germany, killing right and left, in a few years.

A band of young French gentlemen who had defended Toul, near Nancy, seemed to have quite enjoyed the excitement of the siege, and were especially glad that 1,800 poor Germans had been killed by their guns from behind the ramparts. They, too, were anxious to renew the fight in two years or so. At Epernay, the smiling centre of the Champagne wine district, there were 2,000 German troops, and those with whom I spoke were especially dissatisfied with their long absence from home, sweethearts, and wives. Their captain, a very able gentleman, evidently was in favour of three years' service as a *minimum*; and thought that less would not do for a country like Prussia or France, although it sufficed for a small republic like Switzerland; England, he thought, did not require such a stringent system, or, indeed, any obligatory service. The Prussian soldiers costs the state, he said, not more than £30 a year. I did not ask him his opinion of German policy out of delicacy to his posi-

tion. There were numbers of Germans at Meaux, and even at Pantin, the suburb of Paris, made famous by the murder of two years ago. By the-way, I was never asked for any passport, either in Belgium, Prussia, Germany, or in any part of France; although provided with that antique paper before leaving London, and having paid 10s. for the privilege of entering poor France. It does seem needless for M. Thiers to tax his allies of the British islands in this way, when Germans still lie at the very gates of Paris; but no one can understand Thiers, who is, I presume, like many more of his day, without any fixed principles of economy or policy.

And, now, on entering Paris, commenced tales of the terrible years, 1870-71. One lady and her daughter told us how they had begun quite to like horseflesh before the end of the siege; whilst another could never bear to eat such detestable food. There was a chorus among the ladies of detestation of the Commune, and of all those engaged in that revolt. In walking along the streets from the Strasbourg station, nothing was seen until the Boulevards were reached; and then, the Théâtre of the Porte St. Martin was seen in ruins, whilst the gates of St. Denis and St. Martin were covered with marks of rifle balls. Next came in sight the sad ruins of the Hôtel de Ville, and of the Théâtres du Châtelet and Lyrique, and of some splendid shops at the corner of the Rue de Rivoli. Marks of bullets everywhere. A large portion of the far-famed Prefecture of Police burnt, and of the Palais de Justice next were seen. Examination of prostitutes and raids on the young women still go on, as they did before the siege; but I have not yet heard where the examinations are now made. Death and destruction seem to have been everywhere in this still most beautiful of all modern cities. In the Rue Soufflot, the number of bodies carried away, after lying there and in the Place du Pantheon for three days, amounted to some five hundred. I have seen the wall, against which the Communists were placed in batches, and shot, during the live-long May days of 1871. The Luxemburg Palace is intact, but you know that the Tuileries are a wreck, and are being taken down, possibly not to be entirely rebuilt. With the exception of public buildings, there are comparatively few parts of Paris much injured by either the siege or the Commune; and although the people are certainly dull, and a little downcast, Paris is still the charming city that it has always been. It is very healthy, too, just now; only 850 deaths a week, as compared, M. Mauriac says (and I forget my statistics) with some 4,000 weekly in some periods of January last.

I find some of the ablest medical men in Paris quite as anxious to renew the war as the poor soldiers I spoke with in Alsace and elsewhere. One most distinguished gentleman told me in his carriage this morning that he only wished some German would consult him, and he would have him shown to the door at once; and, also, that inoculation experiments on German patients would not be at all disagreeable to him. "*Tantaene animis caelestibus irae?*" I told him that I had no sympathy with any war that I had known of, except the slave war in the United States; but still he asserted that the Germans had behaved so brutally, and robbed so frightfully, that they must be punished *à outrance*. So that we cannot expect, Mr. Editor, that Europe will be a pleasant residence, even perhaps in our quiet little islands, for many a year to come. The first hospital I visited, the Midi, had received many obuses in its gardens, and two had come through the walls, killing two patients, and wounding more; so that seven died of the effects of it. This hospital was used during the siege as a receptacle for poor infirm old men from Bicêtre; and, when the horrible bread of the latter part of the time was given to them they could not eat it, and died 40 per cent. of them of inanition and diarrhoea. This, and such facts, doubtless account for the healthiness of the present moment, as the feeblest died at once in that terrible time. There were many amusing tales by M. Mauriac

and others about the eating of cats, dogs, and other delicacies during the siege. Some liked cats very much, others objected to their flavour; but dogs were much esteemed. As to horseflesh, a beefsteak of the filet is pronounced very good; but the bouillon poor, and stews of horseflesh not good. The largest and best restaurants were open always, and seemed to have had always a good supply of dogs and cats. Everyone cordially curses the recollection of the bread, however. Scurvy was very common.

There was very little venereal disease at Paris during the siege, if we may judge from the consultations at the Hospital du Midi. Thus, according to statistics kindly called for by M. Charles Mauriac, in the months of October, November, December, and January, 1869-70, there were 2,314, 2,198, 1,907, 2,074 out-patients, whilst in the corresponding months of 1870-71, there were only 1,668, 1,658, 1,634, 1,191. In the ten months (beginning with August) 1869-70, there were 21,524 out-patients; whilst in a similar period of 1870-71, there were only 14,705. This of course may be partly owing to the fact that the soldiers were greatly at the ramparts; but, also, because balls and such like places were all shut. I was surprised to find that out of about seventy out-patients there were only one or two cases of indurated sores; all the rest being simple, non-infecting chancres, and gonorrhœa, &c. M. Mauriac praises highly the use of a concentrated solution of chloride of zinc in soft sores. It is, he affirms, by far the best application to that species of sores. Dr. A. Fournier showed me a case of extensive sloughing phagedœna cured in two days by the powder called iodoform at the Lourcine. He praises this remedy very greatly for such cases. Dr. Mauriac's wards at the Midi are in repair, owing to the destruction caused by the siege, and there are scarcely any in-patients at that hospital at present. The Lourcine, however, is full, and Dr. Fournier kindly showed me some most interesting facts as to the analgesia of the skin of the back of the hand and of the mammary gland, &c., in secondary cases of syphilis among his female patients. According to Fournier, chancres of the os uteri, both simple and indurated, are common enough at the Lourcine, and he showed me some wax models of both these affections. He had not yet heard of Mr. Morgan's experiments, and I hope that that gentleman will send his pamphlets to the Lourcine, in order that Dr. Fournier may try to verify his facts in the large field of that hospital. I spoke of them, but, of course, Dr. Fournier was sceptical.

During the siege many bombs fell in the gardens of the Lourcine hospital, and many houses in the neighbourhood were knocked down. Dr. Fournier was at the Ambulances, and was much injured by the cold, which gave him articular rheumatism, laying him up in bed for two months. He was, it seems, the physician of the celebrated Henri Rochefort. I was glad to find M. Fournier an ardent republican, although, as he says, this is a rare enough thing in France. On the other hand, M. Mauriac is sceptical as to republican constitutions succeeding in France; although, of course, he remarked, that it is the best Government for a really free country. However, this may be, we see the words *liberté, égalité, fraternité*, on the walls of the Luxemburg, the Tuileries, and all public buildings, and many hope that at last the republic will succeed. I re-echo that sentiment, for I hear that under Napoleon "none but flatterers and valets succeeded."

There are some of the lectures at the Faculté de Médecine going on just now. Cliniques are held at the Charité, Hotel Dieu, &c., by Gosselin, Pajot, Lasegue, and others, and some lectures are delivered on hygiene, &c. The Ecole Libre, too, is represented by some lecturers; but my short stay in Paris prevented me attending many of these. I was surprised at the Midi to see how much copaiba and cubeba are still used in the out-patients' cases. It seems to me that in London we are not very fond of these drugs now. Also, I regretted to see that

large incisions are still made in cases of suppurating buboes. The system of small punctures on the healthy skin, with pressure, is so very superior, in my opinion, to the "heroic" practice of Ricord. The liquor of Van-Swieten, the pills of pro-iodide of mercury, friction, and subcutaneous injections, are all still in honour in the Midi, but large doses of iodide of potassium are spoken of with very great affection in rupia, in gummy tumours, and in ozena syphilitica. In my next epistle I will, with your permission, give you some more details of a lecture given to the students by Dr. A. Fournier, and relate some of the observations of Dr. Mauriac upon syphilis, and his experiences during the two sieges.

## HOMŒOPATHY—ITS PRINCIPLES EXPLAINED.

(Concluded.)

### LECTURE IV.

THE concluding lecture is devoted to the purpose of answering the objections brought against homœopathy. If our previous remarks will stand the test of logic and truth, this cannot be of much consequence, but as our plan requires it we shall briefly notice them, leaving the readers to judge whether Dr. Epps has brought forward the most weighty, or evaded them and noticed the less important.

I. "The Diet cures the Patient." This Dr. Epps says is "the objection most frequently urged." In reply he says, that those who "believe that diet is the cause of cure are robbers if continuing to give physic."

Of course we are not responsible for the manner in which others use the "diet argument." For our own part we do not propose to assert that diet would cure cases "that had resisted every other kind of treatment;" but perhaps all will allow it may have been the agent in cases in which no other treatment has been tried. We must differ from Dr. Epps, when he tries to brand every man a "rogue" who mentions the diet argument. Dr. Epps asks me if I can account for people getting well under homœopathic treatment. I reply, "Well, many cases which come under a physician's notice merely require attention to diet, and perhaps some cures may proceed from such attention." The incensed homœopath immediately calls me a "rogue," because I use physic, forgetting that in those very cases I should trust to the diet and not give physic, unless required—or that in many cases a little physic would expedite cure. Of course the doctor would not be a "rogue" for giving (and charging for) globules, because they can scarcely be called "physic." The words of Pereira move over are not they cure by diet, but "aided by a strict attention to diet."

II. "Imagination Cures." Dr. Epps says, "this is a better argument; because imagination is indeed a powerful agent; it will explain many cures." He proceeds to relate several cases to prove this, but no one will doubt the point. As he himself acknowledges the fact, we may just ask him, will it not then account for some of the cases attributed to homœopathy? It has been stated on credible authority that the French homœopathic chemists have been selling the sugar globules without submitting them first to the necessary process, or as Dr. Epps would term it, before "medicating" them. If this cannot be contradicted, how can we explain their cures? We do not deny that any man's patients have recovered from imagination, but for the same reason why may not some patients of the homœopaths? Dr. Epps supposes that all his cases were to the allopathists incurable. This is a very gratuitous assumption; we are all aware that very few have derived benefit from any system after a skilful physician has pronounced it hopeless. If he can cure what others cannot, let him prove his power by curing those given up to him as incurable, and not state that patients who go to him in the first instance are incurable by other

methods. Proof, not assumption, is what we ask and it is our due. "Another form this argument takes," says Dr. Epps, "it is faith that cures," and then he goes on to say that "imagination and faith are both valuable auxiliaries." This is just what we say. It may be the cause in some cases. Since the doctor says he cures by them, perhaps he will inform us to what particular diseases diet, imagination, faith, &c., are the homœopathic cures. What diseases do diet, imagination, &c., produce in order to be homœopathic thereto. Oh! Dr. Epps, do you use any agents, the homœopathic action of which you cannot prove, and the homœopathic dose of which you cannot adjust? He declares he can cure "croup," &c., in children when there is no imagination. Many cases of croup will get well spontaneously. Can he cure those that will not? If not his boastings are but empty sounds.

III. "It will do in chronic, but not in acute cases." This is a gross misrepresentation. The only ground for stating such an objection is that some persons have said it would not be right to experiment on those acute cases which without instant relief must die, until we have seen it do some good in those chronic cases in which the experiment can be made without material injury in case of its not succeeding. Ask the patients themselves if this is not right. Would Dr. Epps like to submit himself to any new treatment, at a time when every moment was of vital import?

IV. "Nature" is another "ally" of our opponents, but on what homœopathic principle we are unable to discover. The same remarks apply as under the last head.

V. "Homœopathy has been tried and found wanting." "It was tried, they say, in Paris and in Russia, and it failed." This is a grave objection. It is indeed the whole practical part, and we believe the objection is valid. Dr. Epps says, it "was tried and found wanting by those who wanted to find it wanting, and who themselves wanted the necessary knowledge." But let him remember, a few lines afterwards he shows that though M. Andral was watching the result to form an opinion of its merits, two professors of this doctrine undertook to prescribe, one of whom he informs us "is now practising with great success." If these were not the parties possessed with knowledge who were? He complains that Dr. Bailey's "note-book has been mislaid." We can only assure him that homœopaths ought to have taken their own notes of the cases. He thinks the experiments were not fair, but we can only say that if any results were vitiated by accidental circumstances they should have been noted at the time, and not years afterwards. If they had not deemed it a fair chance for investigation, the professors of homœopathy would not have accepted, or rather petitioned for the opportunity. We have dwelt thus upon this because we esteem it as a fair trial of the subject. Even Dr. Epps cannot complain of the experiments made in Russia; he says nothing about them. These we believe are quite conclusive.

Lastly. Two other objections are produced, viz.:—"Homœopaths are rogues," and it "comes from abroad." As we are not aware of having used these, it is useless to notice his replies to them. We strongly suspect they were invented by the doctor for the sake of getting pity for his persecution, or to show his sound logic in replying to them. To conclude, he tells us who will oppose homœopathy. Of course no man in his senses will do so. But says he, "those who have reached the top of the allopathic tree will." Does he mean those who are the acknowledged physicians of the day and have seen the most practice? "The lazy" will, as if it were harder work to practice homœopathically than otherwise. "The get money men, who sell as much physic as they can." Of course it would not pay to sell sugar globules at the price of physic. "The witty oppose the doctrine, cannot resist the opportunity it affords." No mention of the reasonable. No doubt he thinks that all good reasoners will embrace it, though he only tells us that "children are its friends." Why? because the globules are nice and physic is nasty. Well, very

good. Further, he believes the "fashionable" will befriend it "when it becomes fashionable," and the "public" when they find it "cheaper." That is, we presume, when homœopathic physicians take less fees than others. The book winds up with the names of several homœopaths, a list of their hospitals, &c., and a hope that the doctrine "has taken a hold upon our minds so strong that no antipathic anodynes, nor allopathic counteractions, will be able to drive it from such delightful resting places."

Our task is now finished, and we hope our readers are satisfied. It has required much patience to follow the doctor through his "devious ways." Our chief difficulty has been that he never went straight into a subject, and, according to our plan, we were compelled to "follow our leader." We are not conscious of having passed over a single argument without notice. The soundness of our logic we leave to the reader's judgment. "Personal feeling" has not animated us, at least that we are aware of, but it is very possible that as we follow, every moment expecting to meet with some argument, we have expressed disappointment and even displeasure to see our opponent turn off on some frivolous pretence in quite an opposite direction.

## Correspondence.

### PECULIAR PATHOLOGICAL AND PHYSIOLOGICAL SYMPTOMS OCCURRING IN ONE OF THE LOWER ANIMALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Believing that a case which presents either peculiar pathological or physiological symptoms, although occurring in one of the lower animals, may nevertheless tend to illustrate some function or principle of organic life which may be enjoyed in common by the lowest creature as well as the highest organised being. If you accept this as a correct conclusion, may I ask you courteously to insert in your Medical Journal the following compressed account of disease, with its symptoms, observed in a heifer, sixteen months old. On the 13th inst., when I first saw the animal, she was lying on her side, with the posterior half of her body quite paralysed. She had been in this state about two months. On puncturing her hind limbs with a pin they showed signs of sensibility, but no voluntary motion. With the view of experimenting, gave strychnine daily for a week. On repeatedly pricking the hind parts found complete sensibility, with a slight, though unmistakable degree of voluntary motion, and treading on the hind nails produced twitching of the tail.

On destruction of the animal, found the bladder full of urine and muco-purulent matter, its inner lining being almost similar to a pyrogenic membrane, excepting vascular patches. On dissection, the vertebral column presented signs of disease between the last dorsal and first lumbar vertebrae. Had them removed, believing that here the spinal cord might present morbid features of interest on being submitted to the microscope. I asked Dr. Grey to examine it, who kindly consented to do so. On exposing the spinal cord in his and Dr. Leslie's presence, found in the bollies of the vertebrae a large cavity (as if formed by carious action) communicating with the spinal canal, filled with the *débris* of medullary and osseous matter, with complete obliteration of the cord for three inches, lying on one side, and connecting indirectly the divided ends lacerated. Folds of the investing membranes in their track. No trace of medullary matter or nervous filament. Here they dipped into the orifices of the pillars, the nervous tissue of which was entirely absorbed.

Seeing, then, that the spinal cord was completely divided, it is difficult, nay, if not impossible, to conceive by what means the posterior parts communicated with the brain. That the morbid lesions and phenomena did exist as I have stated, I am prepared to give an amount of reasonable evidence sufficient to satisfy the most incredulous, and should you wish to examine the morbid specimen, it will afford me great pleasure to present it to you.

Yours very respectfully,

J. MOIR, Veterinary Surgeon.

Armagh: 8 Palace row; August 25th, 1871.

## HEALTH OF SOUTHAMPTON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The people of Southampton having passed through a somewhat severe ordeal, may congratulate themselves, on having (they might hope) seen almost the last of small-pox—the number of deaths having dwindled to two *weekly* during the last month—whilst they amounted to *ten* for the two weeks preceding, and to *twenty* for the two previous weeks, making in the aggregate, thirty-eight deaths in the two months.

Hence, there are grounds for satisfaction at the prospect of having seen almost the last of the disease for the present, and for ever beyond an exceptional case, provided vaccination be carried out effectually. But that such an improvement will be effected until the legislature shall have entrusted the carrying out of sanitary measures to a better informed class than at present controls them, it is impossible to entertain the shadow of a hope.

The Doctor would get into a fearful muddle in endeavouring to carry on shop business, or most of the mechanical occupations. So is it with Boards of Health, as at present constituted—for as a general rule, a few intelligent druggists are regarded as authorities, and rule the Board.

EDWIN HEARNE, M.B.

Southampton, Sept. 4th, 1871.

## OBITUARY.

## DR. HYDE SALTER, F.R.S.

A LITTLE while ago we announced the retirement of Dr. Hyde Salter from the Physiciancy to Charing Cross Hospital and the Lectureship in Medicine at the School. We were then aware that the illness which induced him to retire was likely to prove fatal, and that his own prognosis of his case was of the gloomiest. Indeed, the conviction in his own mind that he would not recover was, in the opinion of some of his medical friends, a very unfavourable feature of his case—which, it may be remarked, was of a rather unusual kind, and gave rise to various conjectures as to its exact nature.

Dr. Salter was always delicate. He was a martyr to asthma, the disease upon which he wrote his *magnum opus*. He was, however, the author of other papers—all of them the product of a careful mind—all pre-eminently worthy of attentive study. Some of his revised lectures have recently appeared in a contemporary. His papers in the "Medico-Chirurgical Transactions" are of the very highest value.

Thus passes from us an able physician in his prime. At forty-seven a doctor is young. Had he been spared no one can tell to what height he might have risen; for his compeers in the great world of London all regarded him as sure to advance.

During his last illness he seemed, as we have already intimated, to entertain scarcely any hope of being restored to usefulness, but exhibited at the same time resignation and fortitude.

In private life he was esteemed as an upright man, and the writer well remembers the sentiment of respect inspired by the conviction that he acted in accordance with his convictions, and that his judgment could not be warped by private influence.

## Medical News.

Apothecaries' Hall, London.—At a Court of Examiners, held on Thursday, the 31st August, the following gentlemen, having passed the necessary examinations, were admitted Licentiate of the Society of Apothecaries, viz.:—Messrs. Moses Blok, Charing-cross Hospital; Gordon Cleghorn Day, St. Mary's Hospital; John Jessop, Glasgow School of Medicine; and Horace Turner, of the Middlesex Hospital. And at the same court the following passed the primary profes-

sional examination, viz.:—Messrs. John Batley Bradbury, of the Leeds School of Medicine; Luther Eminson, of University College; Frank Greaves, of the Middlesex Hospital; Montagu H. C. Palmer, of St. Thomas's Hospital; and Joseph Ward, of Queen's College, Birmingham.

**How to Disinfect.**—The following directions as to the mode in which persons and things can be readily and satisfactorily disinfected have been circulated at Oxford:—(1.) Rooms can be disinfected by burning brimstone in them. Doors, chimneys, and windows must be shut whilst this is being done, and any clothes or carpets belonging to such rooms may, previously to further disinfection (for which see below), be with advantage spread out on ropes in such rooms during the process. No disinfection of this kind is thorough if a man can live in the room whilst it is going on. Some volatile agents may perhaps protect against certain infectious diseases; but small-pox and cholera have never been shown to be controllable by such means within rooms occupied by human beings without being at the same time injurious to their lungs and lives. Hence may be seen the inexpediency of recommending for our purposes at the present time certain substances commonly used in such rooms, which may be pleasant as deodorisers, but are known to fail as disinfectants. For living rooms whilst occupied it is all important to insist upon good ventilation, and for such good ventilation it is requisite that all the air of such rooms should be changed. This is best done by seeing that fresh air is admitted as nearly as possible on a level with the ceiling. In every such room one or other of the solutions mentioned below should be placed in any utensil which is liable to be used by any person suffering from any infectious disorder. Thus the evacuations can be disinfected before they can become mischievous. (2.) Water-closets, privies, cesspools, and drains can be disinfected by copperas (sulphate of iron). Carbolic acid can be used with advantage in company with or after, but not without copperas. A certain quantity of disinfectant will disinfect only a certain quantity of foul matter, and disinfection is imperfect till all "hot" smell or alkaline reaction is abolished. For the disinfection of a cubic foot of filth  $\frac{1}{2}$  lb. of copperas, in a couple of quarts of soft water is sufficient. The daily addition by each individual using a water closet or privy of two-thirds of an ounce of solid copperas to such privy, or one-third of a pint of the above solution to such water closet will keep it wholesome, if any accumulation of filth which it may contain or communicate with has been previously disinfected, according to the directions given. Carbolic acid can be used after the addition of copperas till the place smells strongly of it. It should be used in the fluid state, its combination with lime and magnesia having an alkaline reaction, and being, therefore, unsuitable. It may be diluted by being shaken up with twenty times its volume of water, and if poured from a watering pot with a rose nozzle over the sides of a recently emptied cesspool will do great good. Sawdust or sand strongly impregnated with carbolic acid may be used also. Chloralum will acidify ordinary sewage, and destroy its living organism when added in the proportion of one part to forty. It may be expected therefore to act as a disinfectant. This cannot be said of chloride of lime. All water-closets or privies should when epidemics or typhoid fever may be expected be disinfected whether they are offensive or not. It is well at such periods to avoid using any such conveniences which have not been disinfected, especially if, at hotels and railway stations, they may have been used by persons from infected localities. All the conveniences mentioned need ventilation as much as living rooms do. (3.) Body and bed clothes should be disinfected by immersion in Burnett's solution (chloride of zinc), diluted in the proportion of a pint to a gallon of water, and kept in a glazed vessel, by prolonged boiling. (4.) Woollen clothes may be disinfected in an oven at a temperature of 250 deg. Fahr. It is well to burn anything infectious which we can afford to burn.

**Precautions against Cholera.**—On Monday, the first meeting of the sub-committee, appointed to carry out a system of inspection and general sanitary supervision of the port of London, between London bridge and Gravesend, was held. The authorities amongst whom united action will be taken for the prevention of a spread of cholera, through the arrival of any infected ship in the river, are of five classes, viz.:—1st, the Board of Trade; 2nd, the Commissioners of Customs; 3rd, the Trinity Board; 4th, the Thames Conservancy Board; and 5th, the local authorities of the following districts, through which, below bridge, the river Thames flows:—The

City of London, Bermondsey, Rotherhithe, Greenwich, Woolwich, Plumstead, Gravesend, St. Olave's, Whitechapel, St. George-in-the-East, Limehouse, Poplar, and East Ham.

## Gleanings.

### Treatment of Croup by Inhalation of Glycerine.

A GERMAN physician, Dr. Stehverger, recommends the treatment of croup by the inhalation of pure glycerine through one or other of the well-known forms of atomizing apparatus. He was led to try this remedy for croup from observing its good effects in cases of hoarseness and loss of voice. After application, the cough becomes more free and moist, and children are enabled to sleep almost immediately upon being relieved by the inhalation. It is, however, believed to be of no importance to make use of the remedy early and frequently, as, if delayed, it may have no effect whatever. If the glycerine be pure, it may be used unmixed; if not, it should be diluted with a little water. The inhalations are repeated, according to the necessity of the case, at intervals of from half an hour to an hour and a half, and for about fifteen minutes at a time. The effect of the glycerine in this case is supposed to be due to the fact that the secretions of the mucous membrane are thereby increased, and tumefaction reduced.—*Harper's Magazine (Scientific Record)*.

### Influence of the Nervous System on the Temperature and Circulation.

R. HEIDENHAIN (*Pflüger's Archiv*, iii. 504) was led to researches on this subject from experiments made with a view to determine the temperature of the brain in different conditions. He found that the brain always possesses a higher temperature than arterial blood, and that this difference is markedly increased on stimulation of sensory nerves. There is a fall of temperature in the arterial blood, but this does not take place if the spinal cord is severed from the medulla oblongata. Along with the fall in temperature there is increase of blood-pressure. He believes that the fall of temperature is not due to mere disturbance of the circulation effected through the medulla. He finds (in opposition to Dogiel and Kowalesky) that with the rise in arterial pressure, the pressure in the veins is also increased, and *also the velocity of the blood-current*. Hence he concludes that, as the fall of temperature is not due to slowing of the blood-current through the influence of the sensory nerves on the medulla, it must be due to increased radiation from the surface. He finds a confirmation of this view in the fact that, when the body is immersed in a cold bath, the internal temperature rapidly sinks on irritation of sensory nerves, while the reverse is the case in a warm bath where no radiation from the surface is allowed.—*Jour. Anat. and Physiol.*

### Cut the Leaves!

WILL our professional co-temporaries confer a favour on their readers, as well as add to the beauty of their periodicals, by giving a clean cut to their leaves?—*Boston Medical and Surgical Journal*.

### NOTICES TO CORRESPONDENTS.

TO OUR SUBSCRIBERS.—Gentlemen who have not paid their subscription for last year are respectfully reminded of the omission. The Publishers would also be much pleased to receive arrears of subscriptions due for several years previously, which, in *too many instances*, remain unpaid, notwithstanding frequent applications for settlement.

NOTICE.—Subscribers are respectfully reminded that payment by P.O.O., or crossed cheque, is the most convenient and safest mode of remittance. Stamps are unfortunately too easily disposable by dishonest persons.

All valid receipts are given upon printed forms. Subscribers and advertisers are particularly cautioned against making any payments without the production of such a receipt. Cheques or P.O.O. should be made payable in England, to A. A. Tindall; in Ireland, to A. H. Jacob, M.D.; in Scotland, to MacLachlan and Stewart.

### NEW READING CASE.

In consequence of the postal restrictions as to stitching the Journal, improved reading cases with twenty-six strings to hold one volume can now be obtained through any bookseller in town or country, price two shillings. The advantages to subscribers are, that each number when received by post has but to be slipped into the cord, no stitching or pinning being required. The Journal is kept flat for reading, and each volume complete for reference. The same portfolio can be used for successive volumes where desired.

### RECENT NUMBERS OUT OF PRINT.

Full price will be given for THE MEDICAL PRESS AND CIRCULAR OF November 23, 1870, and February 1, 1871, on receipt of same with name and address of sender, at the London offices of this paper, 20 King William street, Strand.

"The case of Cholera in London," by Dr. Edmunds, to which was promised insertion in our present number, did not come to hand until Tuesday morning, after the first sheet of the journal was worked. Also received, "On the Treatment of Eczema," being a continuation of the papers on this subject by Mr. J. L. Milton.

### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Report on the Sanitary Condition of the St. Giles', Westminster, District. By Dr. Ross.

Thirteenth Report of the Medical Officer of the Privy Council, with Appendix.

Sanitary Precautions against Cholera. By M. A. B. London: Lewis. Disinfectants; and How to Use Them. By E. T. Wilson, M.B., F.R.C.S.

Glasgow Medical Journal; Pacific Medical Journal; The Practitioner; Boston Medical Journal; British Journal of Dental Science; Le Mouvement Medical.

### VACANCIES.

Dover Hospital. House Surgeon. Salary to commence at £80, with residence, &c. (See advertisement.)

Islington. Vestry of St. Mary. Medical Officer of Health and Analyst. Salary £250 per annum. Election Monday, 18th inst.

Southwark. St. Saviour's Union. District Medical Officer. Salary £130.

Canterbury Hospital. Assistant House-Surgeon. Salary £50, with board.

Bristol Lunatic Asylum. Assistant Medical Superintendent. Salary £70 per annum, with board and residence.

Towcester Union. Medical Officer. Salary £110, exclusive of fees.

Reeth Union, Yorkshire. Medical Officer. Salary £22 10s., with extras.

Northern Hospital, Liverpool. Physician.

Cork. Medical Officer of Health.

Exeter Dispensary. Surgeon.

North Riding Infirmary, Middlesbrough-on-Tees. Medical Officer.

Westmeath County Infirmary, Mullingar. Surgeon.

### APPOINTMENTS.

ALEXANDER, R. G., M.B., Physician to the Infirmary, Bradford, Yorks.

CURRAN, H. G., Medical Officer for District No. 2 of the Bodmin Union.

MACLEWAN, W., M.B., Casualty Surgeon to the Glasgow Police.

MACLACHLAN, J., M.D., Medical Officer of Health for Walsall.

MOORE, S. W., L.R.C.P.Ed., Lecturer on, and Teacher of, Physiological Chemistry at St. George's Hospital.

MORISON, Mr. R. P., House-Surgeon to the Hereford Infirmary.

PAYNE, G. S., M.R.C.S., House-Surgeon to St. Bartholomew's Hospital.

SHEPMAN, Mr. G. W., Surgeon to the Grantham District of the Great Northern Railway.

THOMAS, W. H., Medical Officer of Health for Maesteg, Glamorganshire.

GREENHOW, E. H., M.D., F.R.C.P., F.R.S., a Physician and Lecturer on the Practice of Medicine to the Middlesex Hospital.

MORRIS, H., M.B., University of London, M.R.C.S., an Assistant Surgeon and Joint Lecturer on Pathology, and Teacher of Bandaging and Minor Surgery at the Middlesex Hospital.

LOWNE, B. T., M.R.C.S., Lecturer on Physiology, including Practical Physiology, at the Middlesex Hospital.

MANSON, A. J. Dr., and CLAYTON, J. Dr. Visiting Physicians of the Banff District Lunatic Asylum.

HARRIS, J. A., M.B., London, M.R.C.S. Eng., Assistant Medical Officer to the Mill-road Workhouse, Everton, West Derby Union.

## Deaths.

BEBBINGTON.—On the 22nd ult., Thomas Bebbington, L.F.P. and S. Glas., of Great Howard street, Liverpool.

BARRACK.—On the 21st ult., Dr. Alex. Barrack, of Cambewell, aged 71.

BOLT.—On the 23rd ult., at Ramsgate, R. A. Bolt, M.R.C.S.E., of Blackman street, Southwark.

ELLIS.—On the 21st ult., J. R. Ellis, M.R.C.S., of Mirfield, Yorkshire, aged 37.

FAVELL.—On the 25th ult., W. Favel, M.R.C.S., of Sheffield, aged 75.

GREENHILL.—On the 20th ult., Duncan Greenhill, L.F.P. and S. Glas., of Main street, Rutherglen, Glasgow.

GRYLLS.—On the 1st of July, at Coacanada, Madras, W. R. Grylls, M.R.C.S., Civil Surgeon, late of the Enniskillen Dragoons, aged 41.

KNOWLES.—On the 26th ult., Edmund Yalden Knowles, M.R.C.S.E., of Parnham, Surrey, aged 58.

SALTER.—On the 30th ult., at Harley street, W., Henry Hyde Salter, M.D., B.A., F.R.C.P., F.R.S., &c., Senior Physician to Charing cross Hospital, aged 47.

## Advertisements.

### APOTHECARIES' HALL, BLACKFRIARS.—

The next EXAMINATION in ARTS will be held at the HALL on FRIDAY and SATURDAY, the 29th and 30th SEPTEMBER, 1871. A Syllabus of the Subjects for Examination may be had on application.

An Examination in ARTS will again be held in the month of JANUARY, 1872.

R. H. ROBERTSON, Secretary to the Board.

**PRIZES IN MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.**—The next Examination for the Society of Apothecaries' Annual Distribution of Prizes in Materia Medica and Pharmaceutical Chemistry will be held at the Hall of the Society, on Wednesday the 18th and Friday the 20th of October, at 10 A.M. The Prizes consist of a Gold Medal and a Silver Medal with a Book. Gentlemen intending to compete for these Prizes must send a written notice of their intention to the Reader, before the 7th day of October, which notice must be accompanied by evidence of their being in attendance on the Third Winter Session of their Medical Studies.

By order of the Court of Assistants,

R. B. UPTON, Clerk to the Society.

Apothecaries' Hall, London,  
August, 1871.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

**FIRST OR PRIMARY PROFESSIONAL EXAMINATION** for the LICENCE.—The next Examination will commence on MONDAY, OCTOBER 2nd. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.

**SECOND OR PASS EXAMINATION** for the LICENCE.—The next Examination will commence on MONDAY, OCTOBER 9th. Gentlemen who have completed four years of Professional Study according to the College regulations are eligible for admission to this Examination. Registered Medical Practitioners, qualified before January, 1861, are admitted to examination under special by-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the by-laws are to be left at the same time.

Fall Mall East, 1871.

H. A. PITMAN, M.D., Registrar.

### CHARING CROSS HOSPITAL SCHOOL OF MEDICINE.

The WINTER SESSION will commence on MONDAY, the 2nd of October.

An Introductory Address will be given by T. HENRY GREEN, M.D., at 8 p.m.

The New School Buildings afford every convenience for study, and the increased hospital accommodation has greatly augmented the means of clinical instruction.

Three Resident Medical Officers are selected from among the Senior Students every six months.

Fees, including Matriculation, £76 5s., which may be paid in five instalments.

Further information and prospectus may be obtained by application to the Dean, at the Hospital.

A. J. POLLOCK, Dean.

### ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.

The WINTER SESSION will commence on MONDAY, October 2nd.

Students can reside within the Hospital walls, subject to the College regulations.

For all particulars concerning either the Hospital or College, application may be made, personally, or by letter, to the Resident Warden of the College, or at the Museum or Library.

A Handbook will be forwarded on application.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH.**—Notice is hereby given that the Preliminary Examinations in General Education by the Royal Colleges of Physicians and Surgeons of Edinburgh, during the Session 1871-72, will be held on the following days, viz.:—Saturday, the 21st of October, and Saturday, the 4th November, 1871, and Saturday, the 20th April, and Saturday, the 20th July, 1872, at 12 o'clock noon, and on each occasion the Examination will be continued on the following Monday at 1 o'clock. The Examinations are held alternately at either College.

Intending Students of Medicine are reminded that they must pass the above Examination, or one of those recognised by the General Medical Council of Education and Registration as equivalent to it, before they can be registered as Medical Students.

Information as to the Subjects of Examination, Books prescribed, &c., may be obtained, on application, from the Officer of either College.

D. R. HALDANE, Sec. Royal College of Physicians.  
JAMES SIMSON, Sec. Royal College of Surgeons.

### ST. THOMAS'S HOSPITAL.

**THE MEDICAL SESSION** for 1871 and 1872, will commence at the NEW HOSPITAL on the Albert Embankment, Westminster Bridge, S.E., on MONDAY, the 2nd OCTOBER, 1871, on which occasion an INAUGURAL ADDRESS will be delivered by MR. LE GROS CLARK, at Two o'clock, after which the DISTRIBUTION OF PRIZES will be made by SIR FRANCIS HICKS, Treasurer.

Gentlemen entering have the option of paying £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105, at once of becoming perpetual Students.

#### PRIZES & APPOINTMENTS FOR THE SESSION.

First Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, and £5.

THE WM. TITE SCHOLARSHIP, founded by Sir Wm. TITE, C.B., M.P., F.R.S., the proceeds of £1,000 Consols, tenable for three years, is awarded every third year.

Second Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, £5. The DRESSERSHIPS, and the CLINICAL and ONSTETRIC CLERKSHIPS.

Third Year's Students. WINTER PRIZES—£20, £15, and £10. MR. GEORGE VAUGHAN'S CHESELDEN MEDAL. THE TREASURER'S GOLD MEDAL. THE GRAINGER TESTIMONIAL PRIZE. THE TWO HOUSE PHYSICIANSHIPS. THE TWO HOUSE SURGEONIES. THE RESIDENT ACCOUCHEURSHIPS. TWO MEDICAL REGISTRARSHIPS, at a Salary of £40 each, or one at £80, are awarded to 3rd and 4th years' Students, according to merit.

#### MEDICAL OFFICERS.

Honorary Consulting Physicians.—Dr. Barker and Dr. J. Ridsden Bennett.

Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Murchison, Dr. Barnes, Mr. Le Gros Clark, Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. Liebreich, Dr. Stone, Dr. Ord, Dr. John Harley, Dr. Payne, Dr. Gervis, Mr. MacCormac, Mr. Francis Mason, Mr. Hy. Arnott, Mr. J. W. Elliott

Medicine.—Dr. Peacock and Dr. Murchison. Surgery.—Mr. Le Gros Clark and Mr. Sydney Jones. General Pathology.—Dr. Bristowe. Physiology and Practical Physiology.—Dr. Ord and Dr. John Harley. Descriptive Anatomy.—Mr. Francis Mason and Mr. W. W. Wagstaffe. Anatomy in the Dissecting Room.—Anatomical Lectures.—Mr. Rainey and Mr. Wm. Anderson. Chemistry and Practical Chemistry.—Dr. A. J. Bernays. Midwifery.—Dr. Barnes. Practical and Manipulative Surgery.—Mr. Croft and Mr. MacCormac. Physics and Natural Philosophy.—Dr. Stone. Materia Medica.—Dr. Clapton. Forensic Medicine and Hygiene.—Dr. Stone and Dr. Gervis. Comparative Anatomy.—Mr. C. Stewart. Ophthalmic Surgery.—Mr. Liebreich. Botany.—Dr. Wale Hicks. Dental Surgery.—Mr. J. W. Elliott. Demonstrations Morbid Anatomy.—Dr. Payne. Mental Diseases.—Dr. Wm. Rhys Williams. Geographical Distribution of Diseases in England and Wales.—Mr. A. Haviland.

R. G. WHITFIELD, Medical Secretary.

T. B. PEACOCK, M.D., DEAN.

For entrance or Prospectuses, and for information relating to Prizes and all other matters, apply to Mr. WHITFIELD, Medical Secretary, The Manor House, St. Thomas's Hospital, Newington, Surrey, S.E.

### ROYAL FREE HOSPITAL, GRAY'S INN ROAD.

#### MEDICAL OFFICERS.

Physicians—Dr. O'Connor, Dr. Cockle, Dr. Rickards.

Surgeons—Victor de Méric, F.R.C.S., Alex. Marsden, F.R.C.S., F. J. Gant, F.R.C.S., J. D. Hill, F.R.C.S.

There being a wide field for Medical and Surgical Practice at this Hospital Students have excellent opportunities of obtaining a bedside knowledge of Medicine and Surgery, and for the study of Pathology, and prepare for examinations by attending a course of three or six months' Clinical Instruction.

Vacancies for Clinical Clerks and Dressers.

For particulars apply to the Hon. Sec. of the Medical Staff, at the Hospital, daily at 10.30 A.M. precisely.

#### PUBLIC SCHOOL EDUCATION IN IRELAND.

### COLLEGE OF ST. COLUMBIA, RATHFARNHAM, COUNTY DUBLIN.

VISITOR—THE LORD PRIMATE.

The College is intended for the Education of Boys from the age of nine years and upwards. The Course of Instruction is of the same nature as that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics, English, French, German, Drawing, and Vocal Music.

Boys are prepared for the Universities of Dublin, Oxford, and Cambridge, or for the Military and Civil Service.

Terms for Boarders—Sixty Guineas. A limited number of Sons of Clergymen can be received at Forty Guineas.

There are two Exhibitions attached to the School, tenable at the University of Dublin, value not less than £20 a year.

Lists of the School, and of recent honours gained by former pupils, together with all other particulars, may be had on application to the Rev. ROBERT RICE, M.A., of Christ Church, Oxford, Warden; or at Messrs. HODGES, FOSTER, & Co.'s, Publishers to the University, 104 Grafton Street, Dublin.

The Summer Vacation ends on August 16.

## Original Communications.

### CASE OF CHOLERA IN LONDON.

By JAMES EDMUNDS, M.D., L.R.C.P., Etc.,  
Late Senior Physician to the British Lying-in Hospital.

The following report will be of interest at this juncture.

The patient (William C.), was a respectable married man, twenty-eight years of age, residing at 65 Charlotte street, Portland place, and by occupation a storekeeper at a builder's yard, near Regent street. His occupation kept him so much at the yard, that he took some of his meals there, and was in the habit of using water from a pump to make his tea with. The attack of cholera supervened on the night of Monday, August 14. On that morning he had his breakfast at the yard as usual, and afterwards returned to his home in order to go with an excursion of the Fitzroy Band of Hope to some grounds connected with *The Green Man*, at Whembley hill, near Harrow. They went by rail from Euston square, and arrived at Whembley hill soon after eleven o'clock a.m. The patient spent the morning with the children, and joined actively in their amusements, including several games of cricket. He made his dinner from food brought from his own house, but he bought a bottle of lemonade at *The Green Man*, and afterwards got the bottle filled with water twice from the bar. He states that this water was very foul and so nasty that some of the excursionists spat it out, and others refused to drink it, or disguised it with sherbet powder. He then tried a bottle of ginger beer which he also thought nasty. During the afternoon he was several times dreadfully griped, and had copious watery dejections. Still he played at cricket and skittles very actively all the afternoon, and drank more water. At five o'clock he had tea, supplied by *The Green Man*, and probably made from the same water. After tea he was several times griped, but not again purged, and he returned home by train at 8.15 p.m. In the train he felt generally unwell and very

sick, but he reached home at 9.30 p.m. without vomiting or dejection. Immediately after reaching home he was dreadfully purged and vomited, the evacuations being discharged "like water from a tap," this occurred continually, and about 11 p.m. while making his way to the closet he was obliged to stop in the passage and vomit on to the floor. He emitted "fully a quart of fluid quite watery and tasting slightly bitter," after this he got into bed, he then vomited twice into a basin, and about 11.30 he was seized in the left leg with cramp so painful as to make him jump out of bed. While sitting on the side of the bed he vomited again, and reaching towards the basin he fainted and fell over it. His wife got out to help him, and when he recovered he drank a large quantity of cold water and returned into bed. From that time he was excruciated with cramp across the stomach and in the legs. He was also purged from twelve to twenty times more, but being unable to rise the dejections passed under him. The people in the house ran to all the neighbouring medical practitioners, but unfortunately could get no one to come; about two o'clock the father arrived and he called me up. I knew nothing of the patient, and had never attended any of his friends professionally, but hearing that it was a case of cholera I dressed and went at once. As nearly as practicable I have, up to this point, recited the words of the patient and his friends. They are intelligent and reliable people.

It was about half-past two o'clock on Tuesday morning when I saw the patient. The shrunken livid face and the characteristic hoarseness of the voice were so marked that, having seen a great deal of cholera, I had no need to ask myself the nature of the disease before me, and I addressed myself to investigate the probable origin of the disease, so as to look after the safety of others. The water in the house proved excellent, the cistern was lined with concrete and, having no waste pipe, was exceptionally safe from contamination with sewer gas. The basement also appeared free from bad smells or sanitary defects, and the only points on which I could fix were the pump water at the builder's yard, and the foul water at Whembley hill. I then examined the patient more minutely. A utensil half full of rice-water vomit stood on a

chair by his side, and on lifting up the clothes from the foot of the bed I saw the body resting in a pool of dejection of a similar character. I dipped out a saucerful of this fluid from between the patient's thighs; and it proved to be characteristic rice-water discharge. There were also the low hoarse voice, the sunken areolæ round the eyes, the pinched livid countenance, the cold whitish ears, and agonising muscular cramps. The case was certainly one of true cholera, and one in which probably a few more discharges would cause hopeless collapse, but I learned that he had joined a Band of Hope at ten years of age, and since then had taken no intoxicating liquors, while his parents were also old abstainers. Of course these antecedents were immensely in his favour, and being a man of small lithe active frame, I thought he would rapidly rally, if the effusion of blood-fluid were stopped. I therefore prescribed the following medicine which I have long relied upon in such cases:—

Spir. chloroformi, ʒj.; acid. sulph. dil. ʒss., misc.

Take thirty to sixty drops in water every ten or fifteen minutes until the discharges are checked. He was also to suck ice and drink pure cold water *ad libitum*, and though the feather bed was saturated with choleraic dejection, I directed him to be well covered up and to remain where he was, the limbs to be carefully chafed, without exposing him to the cold, and a free current of fresh air to pass through the room. He was to take no other drugs and no alcoholic liquor. At four o'clock I saw him again, he had vomited after the first dose of the medicine, but not since, and the dejections were less frequent, and the cramps less distressing. They had carried out the treatment well. The father was to call me up and report progress at six o'clock, I learnt that the cramps were still distressing, but otherwise that he was better. To give the drops more largely and drink the iced water very freely, to continue the other treatment and to take no food. At 10.30 I saw the patient again in company with Dr. Buchanan, who, having seen the case announced in that morning's *Times*, dropped in at my house after breakfast to ask how the patient was going, and I induced him to visit the case and investigate the circumstances. The patient was immensely better, and had taken about eleven drachms of the medicine before they stopped it. There had been neither purging nor vomiting for some three hours, and he had kept down a great quantity of water. He had passed no urine. In reference to the question of infection Dr. Buchanan urged that, as soon as the patient could be moved, the bedding should be destroyed, instead of any attempt being made to disinfect it. This point had not yet arisen, but I at once concurred in the suggestion, and the friends undertook to have the bedding destroyed when the time arrived. Dr. Buchanan also advised that the strong white carbolic acid should be used instead of the common article for disinfecting the discharges. This seemed almost an unnecessary precaution, but it also was adopted. I ordered the patient to take no more medicine unless the discharges recurred, to lie scrupulously still in bed, and go on as before. But if his stomach continued quiet to drink cold barley water gradually strengthened with a little good milk. Dr. Thomas Stevenson, Health Officer of St. Pancras, having seen the announcement in the *Times*, also called upon me about one o'clock, and I invited him to see the patient and accompanied him to the house. The patient was still better and his voice was now almost natural. To continue the same treatment. I saw him several times during the after part of the day, he went on well, but had a great deal of rumbling in the bowels and was very prostrate. At night he had that hebetude of countenance and ferretty sclerotic which ushers in the reactionary fever of cholera. He had passed no urine. To continue the barley water and milk, and to go on precisely as before. He slept well that night.

On Wednesday at 3 a.m. he passed "quite a quart" of urine with some scalding. It was "very dark and thick," it had been carbolised and thrown away, so that I did not see it. On Wednesday night he passed "a pint and a

half more dark but clear." He slept badly that night and had much rumbling in the bowels.

On Thursday morning he passed about a pint of urine. The heaviness of features and redness of the eyeballs having pretty well cleared off, he was shifted into another bed in the next room. The Marylebone Sanitary Inspector immediately afterwards saw the bedding and took it away to destroy it. The bowels acted of themselves on the fifth day, the motion being described as small tape-like matter. Afterwards the motions became normal. He was kept in bed some days longer, and then gradually got about his room. He was confined rigidly to milk and farinaceous diet till the eighth day, when broth and vegetables were added, and he was left to return to his ordinary diet gradually and report progress to me.

On Friday, August 25, he reported himself at my house, it was then the twelfth day of his illness. He was weak and very pale, but going off to Torquay next morning. He has since written to say that he is convalescent.

This patient took no alcoholic liquor during the attack or in his convalescence. It will also be observed that he took no drugs, except during the first four hours of my attendance, when the sulphuric acid and chloroform were energetically administered.

The practical treatment of cholera is a subject to which my attention has been actively called. I saw much of the epidemic in Whitechapel, in 1849. In the autumn of 1853 I was sent by the General Board of Health to Newcastle, and there I had charge of the notorious and filthy district called Sandgate, the focus of an epidemic that killed over 1,000 persons in eleven days. Afterwards I was sent to Dundee on similar duty, and some years later I had charge of cholera wards in Whitechapel. Having also seen a full proportion of cases in private practice; the subject is one in which I have had unusual experience. The following seem to me to be the practical points:—

1. To maintain the warmth of the body by proper clothing, avoidance of exposure, and heated applications if necessary.
2. To economise the muscular power by keeping the patients in bed, and not allowing them to rise for the discharges.
3. To promote the circulation by rubbing the limbs. This must be done carefully as the patients have little feeling on the surface of the body. I have often seen the skin actually rubbed off their limbs by friends in their anxiety to relieve the excruciating cramps.
4. To restrain "the rapid current of fluid from the blood into the intestinal canal." It may be argued that this current is "a salutary effort of nature" to expel a morbid poison, but certain it is that the patient is too often killed by the effort, and that the drain of fluid produces an abnormal condition of blood, and is followed by stoppage of the circulation at the pulmonary arterioles. Whether this stoppage occur from the blood being too thick to pass, or from the arterioles being tetanised by a hypothetical morbid poison, is much the same as the difference between tweedle-dum and tweedle-dee. Probably the abnormal state of the blood and a tetanised state of the arterioles are both factors in the stoppage. In my hands the dilute sulphuric acid given in full and frequent doses has proved the best means of checking the osmotic transudation of liquid, while drinking iced water has been the best means of restoring the fluidity of blood.
5. To relieve the cramps and thus prevent exhaustion, chloroform—the most active and diffusible of the antispasmodics—is the safest and most efficient remedy, and I now never administer any alcoholic liquor, or opium, or any other drugs.
6. While vomiting continues, the administration of food is useless and mischievous, rest is the one thing wanted in addition to the other points.

In the case here reported, the symptoms of collapse followed step by step upon the emission of fluid from the blood and the symptoms passed away, as these emissions were checked and as fluid was reabsorbed. I believe this

fairly represents the history of all cases in which the symptoms are those of pure cholera in a subject of sound constitution, well conditioned tissues, and vigorous age. Under other conditions the pure symptoms of cholera do not develop themselves, and the case is blurred by anomalies, which, though incidental to the attack, are really due to defects of the patient's constitution. Thus, in extreme temperatures, subjects who are aged or weak-hearted, or whose tissues have been damaged by the use of alcohol often die from syncope after discharges that would not have seriously disturbed a healthy subject at an age more tenacious of life. Only the night before my patient was attacked, a widow, over sixty years of age, died from cholera close by at 75 George street, Euston road. In the same house there was then convalescing from cholera a younger woman, a member of the same family, who had been attacked just as badly a week before, but had survived, doubtless, owing to her comparative youthfulness and greater vitality. In the epidemic of 1853 I remember a publican and his wife in the Whitechapel district who died in the same night after a very few hours' illness from cholera with comparatively little purging. But the fact was that they were both past middle age, and, though ruddy, and what is called healthy-looking, their tissues were so unsound that they at once broke down under the onset of the disease. Such casualties often throw valuable light upon the disease itself, but they do not furnish the materials for its true theory.

## CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE XII.

*Chronic Inflammation of the Cervix Uteri—Induration of Cervix—Treatment of, by Potassa fusa, by Local Blood-letting—Endo-metritis—Endo-cervicitis.*

In my last lecture I gave you an outline of the natural history and treatment of the severe and more acute forms of inflammation of the cervix, terminating in congestion and thickness of the mucous membrane lining its canal, and of the follicles with which that membrane is studded, while its vaginal portion denuded of its epithelial coat is covered with numerous vascular papillæ; these little bodies projecting as they do from a rough and abraded surface, which secretes a copious muco-purulent discharge, have been mistaken for granulations. The term ulceration is generally applied to the condition I have described, a term, the correctness of which is very doubtful, there being no excavation and but little loss of substance present, while the discharge is merely the ordinary product of inflammation of a mucous membrane.

I shall now proceed to direct your attention to those still more common cases of what we must call chronic inflammation of the cervix. In it you have considerable thickening and induration of the whole substance of the cervix which feels hard, and frequently is very sensitive to the touch. A vaginal examination or the introduction of a speculum causing considerable pain, while sexual intercourse may for the same reason be unbearable. We frequently find this condition associated with flexions of the uterus, when these occur the fundus generally participates in the sensitive condition of the cervix.

On exposing the cervix with a speculum, its surface will frequently be found to present its normal appearance. If any ulceration exist it will generally be confined to a narrow rim surrounding the os uteri, which is frequently patulous, and in women who have borne many children

sometimes nodulated and irregular, this condition being apparently due to the slight lacerations which may have taken place during labour. In addition you not unfrequently have the glary discharge pathognomonic of disease of the cervical canal issuing from the lips of the os uteri. These cases of chronic inflammation and induration of the cervix, with little or no abrasion of the mucous membrane are met with constantly, especially among women of the lower class, who leave the recumbent posture and engage in their ordinary avocations a few days subsequent to delivery or abortion. But it is far from being restricted to them; you will met with numerous examples of it in the upper classes also.

I do not think that there is any affection more distressing than chronic inflammation of the cervix. The pain in the back, the ovarian pain, and the pain felt along the inside of the thigh, is often even more severe than that experienced in the acute form. The unfortunate patient never seems to lose it even for a day, while it is sure to become aggravated by fatigue, by exposure to cold, and by the approach of each menstrual period. In addition irritation of the bladder manifested by frequent desire to micturate often becomes a very troublesome and distressing symptom. This symptom as pointed out by Dr. Churchill is one common no doubt to other affections of the uterus, but I think I have observed it more frequently in conjunction with chronic inflammation of the cervix than with any other. In fine though not likely in itself to shorten life chronic inflammation of the uterus often renders the patient little better than a confirmed invalid, and makes life itself a burthen.

The constant distress and even actual pain which patients suffer when labouring under chronic inflammation of the cervix, frequently gives rise to the suspicion of the existence of cancer; but the mobility of the uterus, the absence of hemorrhage, and of a fœtid discharge, will generally enable you to assure your patient that, though likely to be for a long time a sufferer, she is not labouring under malignant disease. The induration too resulting from chronic inflammation of the cervix is very different from that caused by the deposit of cancerous matter, the surface of the former being smooth, of the latter nearly always nodulated and frequently presenting at one point a sharp well-defined edge, indicative of the existence of cancerous ulceration. I have known the irregular feel which the os uteri sometimes communicates to the finger when induration has occurred in a woman who has borne many children, to be mistaken for that due to the existence of malignant disease, but these irregular projections surrounding as they do the os uteri, are very different in feel from those produced by cancer. The induration which takes place in cases of chronic inflammation of the cervix, is according to Dr. Bennet, due to the effusion of plastic-lymph into the tissue of the cervix.

I have already noticed that the occurrence of extensive ulceration of the vaginal surface of the cervix is comparatively rare in these cases, it is not easy to explain this circumstance. I am however inclined to think that the access of the disease is so very slow that while lymph is gradually deposited in the tissue of the cervix, the mucous membrane escapes being implicated; it is different however with respect to the lining membrane of the cervical canal, that is nearly invariably engaged to a greater or less degree, it is not vascular and engorged as in the more acute forms, but thickened and hypertrophied. In fact while in the acute form you have a soft tumified cervix, its surface denuded of epithelium, and secreting a copious muco-purulent discharge, the cervical canal participating in the disease, while menstruation is nearly always profuse; you have in the chronic form, a hard indurated neck, frequently covered with an apparently healthy mucous membrane, while a copious glary discharge indicative of chronic inflammation of its lining membrane is seen to issue from the cervical canal—menstruation being invariably diminished in quantity. These cases have long been the opprobrium of obstetric physicians, while their extreme frequency gives to them an im-

portance which the direct effects they exercise on the duration of life does not warrant.

The modes of treatment suggested for the cure of this affection have been very numerous. Nitrate of silver, nitric acid, the nitrate of mercury, and iodine have been all repeatedly tried with the like result, and that generally is—failure. Equally inefficacious as far as the local disease is concerned, but probably more injurious to the general health, have been the long courses of the iodide of potassium, and of the bichloride of mercury to which patients have been subjected. In my opinion medicines are useless in this disease. The failure of all ordinary means induced Sir James Simpson to try what good could be effected by the employment of the *potassa fusa* applied directly to the indurated cervix. With the view partly of “destroying the indurated tissues by direct decomposition, and partly to soften down the remainder by new inflammatory action.” He found it “far more manageable, speedy, and certain than any other method.” I have myself used the *potassa fusa* with great success, for the destruction of indurated growths springing from the surface of the cervix, and I have never seen any unpleasant consequences resulting from its application. I do not however rely on it in cases of chronic inflammation of the cervix; still I should not hesitate to use it, did the means I usually employ fail to effect good results.

Whenever this caustic is used it should be applied through a glass speculum, and be rubbed freely against the part till you are satisfied that the tissues have been destroyed to a considerable depth. The vagina must then be washed out with vinegar to neutralise any of the potash which remains, and which otherwise would irritate that canal. The process can be repeated after the interval of a week or so if necessary. I find however that so much relief can be obtained by repeatedly puncturing the cervix and abstracting by this means blood locally that I generally practice, as you all are aware, this treatment in preference to any other.

Let me call your attention to some of the cases which have recently been treated in this manner in our extern department. M. W., five years married has never been pregnant. For two years past she has suffered constantly from pain in left side, from pain along the edge of the false ribs on that side, and from the back-ache, pain always more severe before and during each menstrual period; the flow has greatly diminished in quantity, and is still gradually lessening; cervix elongated, indurated, thickened, and very tender to the touch; copious cervical catarrh present. The diagnosis was obvious, chronic inflammation and induration of the cervix uteri with inflammatory hypertrophy of the mucous membrane lining the cervical canal existed. March 7th.—Cervix punctured and operation repeated at intervals of a week; pain steadily decreased in severity. After the lapse of six weeks she had obtained such relief that she considered herself to be perfectly well, no other treatment was adopted. This patient was not cured, but like most persons of her class could not be induced to continue to attend when once the urgent symptoms were relieved.

Here is another example in which the same treatment was adopted:—Mrs. W., æt. forty, had one child nineteen years ago, never pregnant since. Catamenia regular till seven months ago, since then they have appeared but twice. Complained of back-ache and pain in right side, shooting down into hip; she also suffered from profuse leucorrhœa. Cervix in a state exactly similar with that which I pointed out to you as existing in the last case. She first presented herself on the 22nd of April. On that day I punctured the cervix which bled freely. May 2nd.—Again extracted blood by puncturing cervix; *states that she menstruated two days after last visit.* May 13th.—Much freer from pain; local depletion by puncturing; cervix again practiced; this was treated weekly till the 20th June.—On that day I find the following entry in my note-book:—Is much easier; has menstruated again without pain. June 27th.—Quite free from pain; cervix

still indurated but no longer tender to the touch. Here was a woman in whom previous to the adoption of this treatment menstruation was irregular, scanty and painful, while she suffered constantly from distressing back-ache and left side pain. You have seen the benefit she has derived from it.

But I should only weary you by detailing the particulars of the numerous cases which I have treated in this manner. Most of you have seen them and are capable of judging of the effects for yourselves; but I cannot help alluding to that of one woman whose sufferings were extreme.

J. D., æt. thirty, married seven years, has never been pregnant, for the past year has suffered from constant and severe pain in the left groin, also over left ovary, and above the pubes. Bladder extremely irritable, micturition painful, catamenia very scanty and irregular, sometimes not appearing at all for several months; uterus low in pelvis and very tender to the touch, fundus retroflected. Sexual intercourse has become so painful that she cannot now permit it at all. On the occasion of her first visit, on the 12th of February, I ordered her to have a saline purgative, and introduced a small sized Hodge's pessary hoping that the support it would give the retroflected womb would afford some relief. In this I was disappointed, that organ was too tender to admit of the instrument being worn for any length of time and I had to remove it after the lapse of three days. For the four following months she presented herself at least once a week in the out-patients' room, but her condition did not improve, indeed she became worse and often she could not straighten herself so great was the pain she suffered. During this period I tried every possible form of medical treatment without effect. On the 20th June I decided on puncturing the cervix and from that day she steadily improved. I repeated the operation at intervals of five or six days. After a few weeks she was so much easier that she only attended about once a month. On each occasion the treatment was repeated with marked benefit. Menstruation though scanty appeared at regular intervals and she was so much better as to be able to resume her regular occupation, that of working in a market garden. She presented herself the other day, after an interval of three months. She then stated that the menstrual flow now appears regularly, that she suffers but little pain and can permit sexual intercourse. The uterus is still retroflected and will I believe always remain so, but it is not painful to the touch. It is well worth your while bearing this case in mind. Previous to my practising local depletion I had for four months tried every other means I could think of without affecting the least good. You all have seen the benefit resulting from that finally adopted. This case is instructive too in another point of view, as proving that the patient's sufferings were due to the state of chronic inflammation which was present and not to the retroflexion.

I have hitherto spoken only of inflammation of the cervix uteri and of the lining membrane of its canal, but the fundus though more rarely affected, may participate in the disease, and cases of chronic endo-metritis are by no means uncommon. I wish you to understand that when I speak of endo-metritis I refer to inflammation of the interior of the body of the uterus only, that is of the part lying above the os internum. This term is used by some I think erroneously to include inflammation of the canal of the cervix also. Inflammation of this latter portion should be spoken of as uterine catarrh or perhaps as endo-cervicitis, a term made use of by Dr. Marion Sims, and which I prefer to the former as being more definite.

Endo-metritis may occur in conjunction with, or be independent of endo-cervicitis, the former being the most common. In addition to the symptoms which are almost invariably associated with all the forms of uterine disease we have certain others which I think are specially referable to the inflammation of the body of the uterus. The pain is much more liable to be paroxysmal, the patient will obtain

relief sometimes for days at a time, then her sufferings will return with increased severity, the approach of menstruation being invariably attended with pain while the appearance of the flow generally brings temporary relief. In fact, endo-metritis is one of the causes of painful menstruation, this is pointed out in a former lecture. When endo-metritis is present I have also remarked that pain of an unusually severe character is felt along the edge of the false ribs. I do not remember to have seen endo-metritis in an unmarried woman, while on the other hand cervical catarrh is occasionally seen even in virgins. So much for the general symptoms. The local ones are also sufficiently pronounced; in endo-metritis the fundus is tender to the touch, and frequently retro- or ante-flected, and when this is the case defæcation is often painful, irritability of the bladder also being frequently present; the discharge too is generally sanious, while the introduction of the uterine sound into the cavity of the uterus invariably gives pain, and if its point touch the fundus this becomes very severe. Dr. Routh, in an elaborate and able paper has endeavoured to prove that the portion of the fundus lying between the Fallopian tubes is the seat of a special inflammation which gives rise to symptoms distinct from those met with when other parts of the body are affected. But while admitting that this portion of the uterus is highly sensitive, I am hardly prepared to allow that it can be the seat of disease, the adjacent portion of the mucous lining of the uterus remaining normal.

Whenever endo-metritis exists for any considerable length of time the inucous membrane lining the cavity of the uterus is thickened and is liable to become covered with numerous elevations, sometimes minute, sometimes so large as to be distinctly felt by the finger introduced through the cervix. The occurrence of this condition I have already dwelt on when speaking of menorrhagia, to which it nearly invariably gives origin. We have recently had in our ward a well-marked example of this, I have detailed the particulars of the case in a former lecture (Lecture v.) The patient suffered from such irritability of the bladder that for years past she had been obliged, even during the night, to micturate at least every hour. This was her most distressing symptom, but of even more importance was the menorrhagia which had gone on increasing in severity for ten years and had rendered her perfectly sanguine. In this case I dilated the cervix, passed my finger up to the fundus and found the lining membrane of the cavity to be in a roughened, granular condition. I cauterised the whole interior of the uterus freely with the strong nitric acid, and had the satisfaction of seeing her perfectly relieved from the vesical irritation from which she had so long suffered, and of discharging her after the lapse of a few weeks perfectly cured of the menorrhagia from which she had so long suffered.

In cases then of endo-metritis in which menorrhagia is present I recommend you to dilate the cervix and to cauterise the interior of the uterus with nitric acid, but if menstruation be diminished, I advise you to rely on local depletion, on rest, and on the injection into the cavity of the uterus of a few drops once or twice a week of pure glycerine; but if you do this later you must first take care that the cervical canal is very patulous, for if the fluid have not a free exit you may bring on, as happened in my own practice, a severe attack of uterine colic. I generally inject the glycerine through a *porte caustique*, passing the point of the instrument through the os internum, and then force a few drops of the glycerine through it by means of a small syringe.

But you may, and frequently have, endo-metritis associated with endo-cervicitis, and as the latter is the most obvious, may possibly refer all the symptoms to it, and overlook the existence of the former. Consequently you may be surprised to find when you have cured the cervical affection that the patient's sufferings are not alleviated. Dr. Marion Sims points this out in his work on "Uterine Surgery," and I am able to confirm the accuracy of his observations.

I have recently had under my care an interesting example of endo-metritis occurring in conjunction with endo-cervicitis. In this patient the cervix was slightly ante-flected and the fundus as well as the neck very tender to the touch. The discharge pathognomonic of endo-cervical inflammation was present, menstruation was profuse and its advent attended with much suffering. She also complained of pain along the edge of the false ribs on the left side. The introduction of the uterine sound caused her much suffering, but this was not experienced till the point of the instrument reached the os internum. I commenced my treatment by puncturing the cervix, and thereby relieved the well-marked congestion which existed. I then dilated the cervical canal, introducing for this purpose two pieces of sea-tangle and subsequently cauterised the whole interior of the uterus with the fuming nitric acid. Afterwards I treated her by applying pledgets of cotton soaked in tannate of glycerine to the cervix. Under this treatment she rapidly improved, the endo-cervical inflammation disappeared, the fundus however was still tender to the touch, proving that the endo-metritis was not yet perfectly cured. I now injected a few drops of glycerine two or three times into the cavity, and finally, immediately before the menstrual period again practised local depletion, by puncturing the cervix. The two last menstrual periods have been perfectly free from pain, the flow is normal in quantity, and the infra-mammary pain quite gone. Unfortunately these cases have a tendency to relapse, and in young women such as this patient, the occurrence of pregnancy, or even less marked cause may rekindle all the bad symptoms.

Acute endo-metritis excepting when it occurs after abortion or delivery at the full term is not common. When it does occur it is liable to be mistaken for peritonitis, to which however it presents a marked contrast in two respects—namely, that the pain is nearly always paroxysmal in character, and is generally accompanied by a sanguineous discharge.

The following case presents a good illustration of this affection:—A lady who had suffered from post-partum hæmorrhage, and in whom involution of the uterus had never been perfectly accomplished having been exposed to cold some months subsequent to delivery, was attacked with severe pain in the region of the uterus. There was also well-marked tenderness on pressure over the pubes. This attack took place just before the occurrence of a menstrual period, but the flow, instead of being checked, appeared in increased quantities and continued persistently. This lady resided in a remote part of the country, and I did not see her till after the lapse of about ten days. I found her in great agony, but ascertained that this was not incessant, that she had intervals of nearly perfect freedom from suffering, lasting sometimes for several hours, then the pain would return with great violence. Pressure over the uterus was always productive of distress, and increased the pain, but elsewhere the abdomen was not tender to the touch. The pulse was rapid, but not of the character which accompanies peritonitis; there was no vomiting but a continuous though not copious hæmorrhagic discharge was present. On making a vaginal examination the uterus proved to be tender to the touch; it was evidently enlarged, and on introducing the uterine sound it passed without difficulty to the depth of five inches. I had no hesitation in pronouncing the case to be one of metritis. As already mentioned the pain was of a well-marked paroxysmal character; the tenderness on pressure over the uterus was also present, but if the abdomen were not touched, she would have long intervals of nearly perfect freedom from suffering; then however it would come on and last for hours without intermission, a characteristic of metritic inflammation, to which Dr. West specially alludes in his valuable work on "Diseases of Women." He states that "the tenderness of the uterus in these cases always led him to abstain from measuring its depth by means of the sound." In the case I have just narrated however its introduction caused no pain. The distance at which this

lady resided from town precluded me seeing her again till she was able to travel, which was not for four weeks. On examining her on her arrival in Dublin I was agreeably surprised to find that the uterus, although not of its normal size, was much smaller than I could have anticipated it would be, the cavity measuring about three inches in depth.

In this case I enjoined perfect rest, applied poultices over the abdomen and administered opiates. Leeches could not be obtained or I should have applied three or four. Mercury in such a case as this would have been in my opinion absolutely injurious.

## DIARRHŒA AND CHOLERA :

### THEIR SUCCESSFUL TREATMENT BY MEANS OF THE SPINAL ICE-BAG.

#### A SUMMARY RECORD OF CASES AND RESULTS.

By JOHN CHAPMAN, M.D., M.R.C.P.,  
Physician to the Farringdon Dispensary.

(Continued from Page 199.)

THE principles propounded in the previous part of this paper are sustained by an extensive array of facts and arguments in my work, entitled, "Diarrhœa and Cholera: their Nature, Origin, and Treatment through the Agency of the Nervous System;"\* and to that work I must refer to such of my readers who are disposed to learn what those facts and arguments are. But in order to assure those readers who are not so disposed that the principles in question are fairly established, and are therefore worthy of at least *provisional* acceptance, I am induced to cite an authoritative judgment published in the form of a review of that work, in the *Medical Times and Gazette*, November the 3rd, 1866, and written, as I am enabled to state, by one of the most eminent of English pathologists, whose practical experience of cholera has been peculiarly great, and whose very valuable contributions to the science of medicine, conjoined with his high personal character, ensure him the general respect of the profession. Of the doctrine in question, concerning the nature and causes of diarrhœa and cholera, that "it is in harmony with the results of the most recent physiological investigations," that "it is only by a close examination of the detailed application of the hypothesis as a means of rendering intelligible the proximate cause of every special symptom, that a comprehensive conception of the hypothesis becomes possible," that each special symptom "receives a consistent and intelligible explanation," and that "the strength of the theory lies in its comprehensive and simple explanation of seemingly contradictory phenomena, by the application of a recognised general truth." Knowing that to no other hypothesis yet propounded concerning the diseases in question could these words be correctly applied, and that many thousands of lives now sacrificed every year, might be saved if only we could divine the mystery which has hitherto veiled the real nature of those diseases, I feel constrained to avail myself of the authoritative testimony which these words contain in order to enforce attention to a doctrine which, though revolutionary of prevailing opinions and practices, will, I believe, when once generally recognised, confer a power of preventing and curing those diseases, in the great majority of cases, as easily and effectually as that disease which in many respects resembles them very closely, and which hitherto has defied the power of medical art, viz., sea-sickness, can now be prevented and cured by means of the Spinal Ice-bag.

Assuming the truth of the principles already affirmed, we are led inevitably to the conclusion, that any agent which is capable of abolishing that state of hyperæmia of

the spinal cord and of the sympathetic ganglia constituting, as alleged, the proximate cause of diarrhœa and cholera, is capable of curing those diseases; and that any agent capable even of lessening that hyperæmia, may so lessen the force of those diseases as, in the battle for life, to enable the *vis medicatrix nature* to become victorious.

English summer diarrhœa may, in a large proportion of cases, be completely arrested by suitable medicines, but that in a very large number of cases it cannot be thus arrested is, I presume, fairly proven by its great destruction of life, and especially of infant life, during the months of August and September of almost every year; for I suppose that in the majority of fatal cases, the medical attendants have exhausted their resources in endeavouring to avert death. In England and Wales during the twenty years 1847-66, diarrhœa and cholera destroyed 417,199 persons, and of this vast number about three-fourths, or 311,200, were destroyed by diarrhœa. In London during the twenty-one years, 1847-67, these diseases destroyed 88,247 persons, and of this number nearly two-thirds, or 53,706 were victims of diarrhœa. As is well known, a very large proportion of these victims are children. I should, however, expect, inasmuch as the exciting cause of the summer diarrhœa of infants is in almost every case dental irritation that the disorder when presenting itself in them would be far less amenable to the curative power of any drug, than the summer diarrhœa of adults is actually found to be; and though, so far as I am aware, no statistics have yet been tabulated by which I can test the accuracy of my opinion on this point, I am persuaded of its truth by considering that, whereas the action of any exciting cause of summer diarrhœa in adults is likely to be temporary and easily removeable, the action of the most common exciting cause of the malady in children—dental irritation, is prolonged, and though it may be lessened, is generally irremoveable. Hence it is, I believe, that astringents which, in cases of summer diarrhœa in adults generally act beneficially, prove useless when prescribed for children suffering from the same malady. Acting on this opinion, I am in the habit, when obliged to treat infantile diarrhœa, whether merging into cholera or not, by means of medicines only, of prescribing those which are known to exert a special influence on the nervous system, viz., bromide and iodide of potassium. My experience leads me to believe that these drugs are far more effective than are any astringents, or any eliminants in counteracting the cause of the disorder when a consequence of teething; and were I compelled to trust to drugs alone in the treatment of cholera, I should, with my present knowledge, place my chief trust, which, however, would not be great, in bromide of potassium.

The summer diarrhœa of adults may in many cases be arrested by astringents: chalk and opium very often prove efficient—restraining the discharges, while the proximate cause of the malady subsides; but knowing that, in those cases in which, notwithstanding this treatment, the disease increases, the opium already given is likely to augment its virulence, I, as a general rule, avoid that drug, and have recourse to frequent doses of sulphuric acid with or without *very small* quantities of quinine, according to the peculiarities of the case. And this treatment I find so often successful, and, unlike the treatment involving the use of opium, so free from danger, in cases of simple diarrhœa, that when compelled to trust to drugs only, my main reliance is on sulphuric acid. When, however, decided choleraic symptoms—especially cramps—present themselves, sulphuric acid appears to me for *à priori* reasons (expressed in my work on "Diarrhœa and Cholera") the most dangerous of medicines, and a large experience confirms my theoretical conclusion in the most decisive manner. According to the report of the Treatment Committee of the Medical Council of the Royal College of Physicians, when the different plans of treatment were tested in respect to their relative efficacy in cases of choleraic collapse, it was found that the percentage of deaths following the use of sulphuric acid was 78.9, or 1.3 greater even than that following the treatment by

\* Second Edition, enlarged, in 8vo. pp. 268. London: Trubner and Co.

castor-oil. This conclusion was confirmed by the experience of the cholera epidemic of 1866: Dr. Andrew Clark informed me that, while he had found at the London Hospital, sulphuric acid extremely beneficial in the treatment of diarrhoea, it proved quite the contrary in the treatment of cholera. I may add that the numerous and careful experiments made at that hospital in 1866, in order to determine the efficacy of various drugs said to be curative of cholera, resulted only in confirming the mournful conclusion arrived at during the previous epidemics, viz., that no drug yet discovered exerts any appreciable power in rescuing patients from the state of choleraic collapse.

In several cases I have produced faintness, nausea, vomiting, diarrhoea, sweat, coldness of the surface, and contracted or pinched aspect of the countenance by the application of heat along the spine. In some cases these conditions, or several of them, are induced as accompaniments of the arrest of hæmorrhage (pulmonary or uterine) by the application of the Spinal warm water-bag. Now these experiments prove (1) that the spinal and sympathetic nervous centres can be powerfully affected by the application of heat along the surface of the spine; and (2) that by means of heat thus applied the phenomena of summer diarrhoea and of cholera can, in fact, be artificially imitated in persons of preternatural nervous susceptibility at all events. These experiences also suggest the idea that if heat thus applied will produce these phenomena, their analogues—summer diarrhoea and cholera—are really, as I have already asserted, expressions of hyperæmia of the spinal and sympathetic nervous centres, and that both they and the artificial imitations of them are likely to be abolished by cold applied in the same way. And that cold thus applied will abolish them in my experience, in a large number of cases, enables me to affirm a thoroughly established fact. I have proved over and over again, and many other persons have proved since I first announced the discovery, that when these several symptoms present themselves as the constituent elements of sea-sickness, the nature of which is, as I maintain, very closely allied to that of summer diarrhoea and cholera, they can, as a general rule, be thoroughly subdued by the application of the Spinal Ice-bag. Moreover, when each of these symptoms presents itself associated with some other disease it can, I affirm, be more easily controlled or got rid of by the use of the Spinal Ice-bag than by any other agent; and, as vomiting is one of the formidable symptoms of cholera, I may add that that troublesome form of vomiting so often experienced by pregnant women, and so notoriously uncontrollable by drugs, can be completely put an end to by the Spinal Ice-bag, and, if it be judiciously used, with perfect safety.

The foregoing facts, as well as many others of different kinds, which, if space permitted, I might adduce, justify the expectation that the Spinal Ice-bag will prove a powerful remedy of both diarrhoea and cholera. That it is so I now proceed to show.

#### Cases of Diarrhoea.

CASE I.—Mrs. T. æt. sixty, suffering from diarrhoea, consulted me July 22nd, 1865, 11 a.m. Her bowels had been moved that morning four or five times. She complained of feeling excessively "low" and of slight abdominal pain. She was remarkably pale, and looked very ill. I prescribed the application of the Spinal Ice-bag, containing ice in each of its three cells, along the spine from the middle of the cervical to the middle of the lumbar region, the application to be continued until the symptoms should subside. The bag was immediately applied, but only during one hour. From the time it was applied until 8 p.m. the bowels were not moved at all, and no pain was felt.

Meanwhile she was extremely excited and troubled by hearing a piercing scream from a lady in the same house who had been seriously hurt, and at 8 p.m. the diarrhoea recurred, the bowels being moved again three times.

At 9.30 p.m. the patient went to bed, applied the Spinal Ice-bag by lying upon it and fell asleep. In about an hour she awoke, removed the bag, and then slept continuously till 6 o'clock the next morning.

July 23.—Between 7 and 11 a.m. the diarrhoea returned vehemently, the bowels being moved six or seven times. The patient felt cold; her arms and hands were covered with a cold sweat; the features were sunken; and she felt so ill as to be seriously alarmed. At 11 a.m. the Spinal Ice-bag was applied as before. At first the feeling of coldness seemed to increase, but at the end of ten minutes, her whole body had become warm. "I felt," she said (July 25th), "a glow of heat all over me, which has continued ever since." Meanwhile she had no return of the diarrhoea, and became in all respects quite well.

*Comment.*—This case shows the necessity of continuing to use the Ice-bag for sometime after the bowels have ceased to be moved, otherwise the malady may recur: in fact, such a sedative influence should be made by the ice on the nervous system as will put an end to its excessive stimulation, not only of the mucous membrane and muscular coat of the intestines, but also of the muscular coat of the arteries in all parts of the body. Not until the morbidly excessive energy of the sympathetic ganglia, which holds the arteries throughout the body in a state of spasmodic contraction, has been so subdued as to facilitate the re-establishment of a free and vigorous circulation of blood through the peripheral blood-vessels, is the disorder completely overcome. How admirably the ice fulfils this indispensable condition is well exemplified in this case by the "glow of heat" which the patient felt "all over" her; and my experience justifies me in saying that had she, on the occasion of the first attack, used ice during several hours instead of during only one, the surface "glow" would probably have been induced during the first day, and that the diarrhoea would not have recurred at all.

CASE II.—C. T., æt. forty-four, was attacked July 24th, 1865, with violent diarrhoea. During several days previously he had not felt well, and his bowels had been open more freely than usual. A three-celled Spinal Ice-bag was applied from the middle of the cervical to the middle of the lumbar region. At the time the ice was applied he felt an urgent need to go again to the water-closet, but the first effect of the ice was to cause that feeling to subside. Only in half-an-hour afterwards were the bowels again moved, and from that time he did not experience an unpleasant symptom.

*Comment.*—The "first effect" said to have been produced by the ice in this case is often experienced by patients suffering from diarrhoea, and who use the Spinal Ice-bag, and is a striking exemplification of its power over the nervous system.

CASE III.—D. D., male, æt. forty, consulted me in August, 1866, when he was suffering from diarrhoea, which had continued, more or less, during several days, but which had at length become severe. His skin was cold and peculiarly clammy; his features were pinched and sunken; he was altogether much enfeebled, and his abdomen was especially cold. I ordered heat to be applied over it and to the extremities, and ice to be applied simultaneously and continuously along the spine—the bag to be replenished with ice each time the previous supply should have melted. Ice was thus applied about eight hours uninterruptedly, and afterwards a short interval was allowed to elapse between the application of each bag. The purging became gradually less frequent, and by the following morning had wholly ceased. It was not until the purging, which left him extremely weak, had quite ceased that the surface of the body regained its natural warmth. The patient used the Spinal Ice-bag afterwards during a few days, at increasingly wider intervals, and then left it off. His strength was quickly restored, and he continued quite well.

[CASES IV, V, and VI, which, being described *in extenso*, are peculiarly instructive, I am obliged, owing to want of space, to omit from this narrative.]

CASE VII.—July 8, 1867.—William P.—, æt. seven months, has suffered from diarrhœa during the last six days. Spinal Ice-bag to be applied at frequent intervals till the ice melts, so long as the flux continues.

July 10th.—Ice was applied till it melted only once daily; but the diarrhœa ceased completely on the 6th inst. The child is quite well in all respects.

CASE VIII.—Sept. 14, 1867.—H. B., æt. eleven months, has suffered during the last fortnight from diarrhœa, which, during the last few days, has become increasingly severe. The discharges, the mother says, are almost transparent like water; they are very frequent, but most so in the night. The skin is dry and hot; to apply an eight-inch ice-bag along the whole spine, until the ice has melted, every two hours, and continue to do so till the diarrhœa abates, then gradually increase the time between the applications.

Sept. 18.—The child became much worse before the ice was applied; it was purged at least fourteen times in the daytime of the 14th before the ice was procured. It was applied four times on the 15th. The child slept each time he was laid on the ice-bag over two hours at a time; the bowels were moved about six times. On the 16th the improvement continued; on the 17th he was still better, the motions having more substance in them again, To-day he has had no ice, and is very irritable. The child's mother is greatly astonished by the fact she attests, that on every occasion the child slept on the ice. To continue its use as before.

Sept. 28.—The ice was applied only three times after last visit; the child has had no diarrhœa since, and is well, except that the fœces, which are now quite solid, were tinged with blood to-day. This was also observed before the diarrhœa came on.

CASE IX.—Sept. 14, 1867.—F. S., æt. two years and three months. Has been ill three weeks; became feverish; a week afterwards diarrhœa set in, and has continued with but slight relief from medicine. Four days ago blood and mucous began to appear in the stools, which approach the rice-water character. To apply a ten-inch ice-bag along the whole spine, until the ice shall have melted, three times a day.

Sept. 18.—The ice has been applied only twice a day, but each time until it was melted. The blood disappeared from the stools on the 15th, that was about four motions daily; they are of a more natural character, but still fluid. The child has slept each time the ice has been applied. To apply it four times daily.

Oct. 9.—After last date the ice was used a full week—four times daily, for two or three days, then twice or three times daily. By degrees the diarrhœa lessened, and had quite ceased at the end of the fourth day; since then the bowels have continued quite regular. The child has slept well, and has a good appetite. Her mother says, "She was well contented with the ice, and each time it was applied slept on it."

CASE X.—Sept. 21, 1867.—G. M., printer, æt. forty, began to be ill on the 18th; has been up two nights, nearly the whole of each night suffering from excessive diarrhœa; during the last twenty-four hours has had sixteen motions tinged with blood. He complains of nausea, but is not actually sick. To apply a twenty-four inch ice-bag along the whole spine, till the ice melts, four times daily; oftener if the diarrhœa continues.

Sept. 25.—Applied ice only twice altogether—once September 21st, after which the diarrhœa stopped. It inclined to recur on the 23rd, when the ice-bag was again applied, and again it relieved him at once. On the 21st, the patient slept during the whole time the ice was applied, and a long time afterwards. His wife remarked, "he dropped asleep at once, and he said 'the ice makes me warm.'"

CASE XI.—Sept. 28, 1867.—A. P., æt. twenty-three, has recently suffered from an inflamed breast, and now she is troubled with shingles over the whole body, even

on the scalp, and with profuse diarrhœa, which began at 6 a.m., yesterday. She thinks her bowels have been moved "quite twenty times" during the last twenty-four hours. Fœces very dark and watery; to apply ice along the lower half of the spine continuously until the diarrhœa abates.

Oct. 2.—The diarrhœa stopped completely within three hours from the time when the application of the ice was begun. The shingles also disappeared with almost equal rapidity, and no trace of them remains. The patient feels and looks wonderfully better.

CASE XII.—October 2, 1867.—Gabriel T.—, æt. five, suffering from very severe choleraic diarrhœa. Skin cold, clammy and dark-coloured; features sunken; patient extremely enfeebled. The treatment I prescribed consisted only in the application of a Spinal Ice-bag several times a day, and of heat to the extremities and general surface of the body. At the end of three days from the time the treatment began the patient had completely recovered.

CASE XIII.—E. W., male, æt. nineteen, came to me July 22nd, 1868, stating that he had been suffering during three days from diarrhœa, and that he had about six movements of the bowels a day. He said, "I've awful sharp pains in my inside." Became very cold each night during the attack, up to the time I saw him. I advised the application of the Spinal Ice-bag along the whole spine three times a day until the ice should melt. July 25th.—The patient applied the ice during an hour on the 22nd and 23rd, and yesterday, the 24th, he applied it at 10 a.m., 3 p.m. and 9 p.m. also, during an hour each time. On the 23rd he had about six motions; yesterday three, and to-day none at all. Says that he became very warm after the application of the ice, and felt strongly that he was deriving great benefit from the use of it. He declares that he has not been cold at all during the last two nights. He now looks well and says he feels so.

CASE XIV.—July 29, 1868.—John Tovey, adult, complains of having suffered from diarrhœa during the last three nights—worse at nights. Bowels moved about six times in the twenty-four hours. Breaks out in a cold sweat, after which he shivers. Has become extremely weak. Pulse 60. To apply ice till it melts, three times a day.—Aug. 5. Has used ice six times. Applied it for the first time in the evening of July 29. That night his bowels were not moved at all. On the 30th the bowels were moved three times, and since then, only once each day. Has neither had "the cold sweat" nor the "cold feeling" about his body since. Pulse 68.

CASE XV.—August 26th, 1868.—Ann Ansell, æt. fifty-five, had severe diarrhœa, with cramps, a month ago. Was three days in bed with "dreadful cold perspirations." Says "she felt as cold as a stone." She has never been free from diarrhœa since, and is often purged four or five times a day. Is very weak; no appetite; sometimes feels extremely cold. Apply ice till it melts along lower two-thirds of spine twice a day.—September 2nd. Diarrhœa much lessened. The stools have become more solid. To-day the bowels were opened twice; yesterday, three times. She feels stronger; continue the same treatment during another week. No medicine.—September 9th. Bowels no longer relaxed; treatment discontinued.—September 26th. Has continued quite free from diarrhœa.

A large number of similar cases are scattered through my Case-book, but I have not now time to collect them, or even to ascertain their number. I trust, however, that the foregoing will suffice to produce the conviction that we have within our reach a remedy for diarrhœa which, while not open to any objection of the kind which may be urged against even the most efficacious drugs, is precisely adapted to counteract all the symptoms of the disease, acting directly upon, and restoring to health the nervous centres, the disorders of which originate those symptoms.

I am glad, however, to be able to say that the method of treatment exemplified by these cases has already been

tried and emphatically approved by several medical men, some of whom have supplied me with records of their observations, which I here give in an abridged form:—

CASE XVI. (under the care of Dr. J. C. Williams, of Liverpool).—July 12, 1865.—George B., æt. eighteen months, was suffering from severe diarrhœa. He had been ailing for some time previously. Astringent mixtures proved of no avail; vomiting came on, and by July 28th serious fears for the child's life were entertained by the parents. All medicines were then stopped, and a spinal ice-bag was applied, the child being well wrapped up meanwhile. "While the ice was on the child became quite warm and free from pain, and in fifteen minutes was asleep, whereas it was crying bitterly before the application."—July 29th., 10 a.m.—"After the ice was applied last night the child fell into a comfortable sleep, which continued till 7 o'clock this morning. An hour afterwards the bowels were moved once, a tolerable firm stool. Nothing more was done, and the child remained quite well when I left home, August 9th."

CASE XVII (also under the care of Dr. J. C. Williams).—July 28, 1865.—J. J., male, æt. thirty-seven, was attacked with Summer cholera. I saw him first on the 30th. He was then so bad that I should have considered the cholera Asiatic, but for the bile vomited. He had three doses of chlorodyne to relieve the cramps, and ice was applied to the spine. He was quickly relieved of the vomiting and purging, but the cramps were very troublesome on the 31st. He applied the ice three times, for an hour each time. August 1st.—"Cramps gone; skin warm; bowels not moved; no vomiting, but the patient continues thirsty. Nothing further was done, and he was quickly well."

CASE XVIII.—Dr. J. Moorhead, of Weymouth, in a letter which he addressed to me, Oct. 31, 1865, says:—"Having recently suffered from a most severe attack of diarrhœa, for which I took largely the usual astringents, with opium, but without avail. I applied an ice-bag to the lumbar region, which proved most grateful, and immediately arrested all the symptoms."

CASE XIX. (under the care of Mr. Munro, Director of the Hydropathic Establishment, Melrose, N.B.)—"A very intelligent gentleman, who for a long time suffered from chest disease, had an attack of sickness and diarrhœa." After the spinal ice-bag had been applied to the middle and lower third of the spine during about an hour, while the patient was in bed, "he was able to report the removal of sickness and pain, a warm glow over the limbs, and, ere long, the entire removal of the diarrhœa. On a subsequent occasion, when the same disorder was brought on by over fatigue, the same remedy was employed with like success."

CASE XX.—Dr. H. Fitzgibbon, of the West Indian Steamship, *St. Thomas*, published in the *MEDICAL PRESS AND CIRCULAR*, April 1, 1863, an important case of "diarrhœa" with vomiting, cramps, and abdominal gripings, cured by means of the Spinal Ice-bag. Dr. Fitzgibbon says of the case,—"It seems to me interesting as supporting Dr. Chapman's statement, that cases of diarrhœa which resist the usual treatment, and even threaten to terminate fatally, as cholera, may be subdued by the application of an ice-bag along the spine."

I have been informed by Mr. J. Mardon Wilson, of Philadelphia, that his brother, Dr. Wilson of that city, has found by experience of many cases, that my method of treating cholera infantine is very successful.

Dr. J. S. Hackett, of New Amsterdam, Berbice, British Guiana, has stated in a letter addressed to a friend of mine, that he treated several cases of diarrhœa by means of the Spinal Ice-bag, and invariably with success.

Dr. J. Waring-Curran, has published in the *Medical Times and Gazette*, seven cases of "*Infantile Diarrhœa*," complicated with, or accompanied by, convulsive seizures, and which were treated by the same method. "The result of that experience was," he says, "that I found that the

ice controlled the diarrhœa in a striking manner, and that it ultimately arrested it. Moreover the power of the ice in subduing the convulsions, was most forcibly demonstrated; kept in abeyance when the ice was applied, they recommenced when it was removed."

#### M. GUÉRIN'S MODE OF EMPLOYING COTTON WADDING AS A DRESSING FOR WOUNDS, AND IN AMPUTATION CASES.\*

For several months the sanitary state of the hospitals, and particularly that of St. Louis, was absolutely deplorable; conservative surgery gave the saddest results, and amputations were commonly followed by death. After having vainly sought in the recognised methods of treatment for something which should offer a protection against purulent infection, M. Guérin conceived the idea of a wadding dressing as the remedy which best harmonised with his theory of that disease. We stated before that he views this accident as the result of the contact of the wound with an atmospheric miasma generated by the wounds in the patients' vicinity.

In order to make the wadding dressing, the wound is washed with an antiseptic liquid, then a sheet of wadding is applied immediately upon it; over this more sheets of wadding are rolled so as to envelop the limb in a kind of sheath, as voluminous and even more voluminous than that by which the limbs are protected in Burgrave's apparatus. That done, several rollers are wound round it one after another compressing the whole tightly; the softness and resistency of the cotton allowing of its being tightened as much as one pleases: it is essential to squeeze it as much as possible. When completed the dressing should be hard, it may be struck with the hand.

Once applied the dressing should remain on as long as possible. In amputation cases the mean time has been from twenty to twenty-five days; with some the abundant suppuration, pain, a slipping of the bandages, caused the dressing to be taken off a little sooner; with others it has been possible to leave it on longer, thirty-three days in the case of a child who had undergone amputation.

This dressing, thus constituted, answers three fundamental indications.

It is a dressing requiring to be but seldom renewed. In this respect it excels all others yet invented. For twenty days and more the wound is left at rest, sheltered from all hurtful contact, protected from shocks of any kind.

In the second place, if the air should reach the wound it does so after having filtered through the wadding. It has been ascertained that wadding is an air filter. In all physical or meteorological experiments it is cotton that is employed for this purpose. This enormous mass of compressed wadding appears to realise the ideal filter; it is conceivable that if the air reaches the wound it must do so freed from all the impurities which it holds suspended. Then, the access of air, already rendered difficult by the layer of cotton, is made still more difficult by the secretions from the wound which agglutinate the fibres of the cotton, and drying form a hard crust under the pieces of dressing.

Finally, the third condition to which M. Guérin attaches great importance is elastic compression. In fact, under this cuirass the parts undergo, without pain, an energetic compression. Now compression enjoys powerful antiphlogistic properties, which bear their fruit. This compression being equally diffused over the limb, prevents all chance of strangulation; if pus had any tendency to form in the tendinous sheaths and create purulent dépôts it would constitute a complete obstacle. It is doubtless to elastic compression that one must ascribe the

\* Translate from the July number of the "*Journal de Médecine et de Chirurgie Pratiques*," by FRANCIS M. LUTHER, M.D., Capponquin.

surprising results that when one uncovers the limb, no trace of inflammatory swelling can be perceived.

To these very characteristic properties a fourth ought probably to be added. The parts shut in are constantly maintained at the temperature of the body, perfectly protected from all causes of refrigeration.

The wadding dressing should answer all those indications; to secure its doing so in practice, one must take a great number of precautions, without which success would be absolutely compromised. First, it must be applied upon a much more extensive surface than that of the wound. Thus, for amputation of the foot and leg, the sleeve of wadding must include the thigh; for that of the thigh, the abdomen, and the loins must be included within the layer of wadding; so with the arm. For short stumps and disarticulation of the shoulder extreme attention must be paid to having the mass of wadding considerable, the stump fixed, and the thorax and shoulder enveloped in the wadding. The dressing must be inspected daily, for it loosens with much facility. A bandage has then to be wound over all, tightened and fastened with pins, and if it is supposed that air can get in at top, fresh sheets of wadding must be superposed and again rollers.

Although in those conditions little pus is found upon the surface of the wound, yet it is well to moisten the dressing every day with some disinfectant solution, for the fluids soaking through the cotton, on arriving at the exterior surface of the dressing, putrefy upon contact with air, and may give a bad smell.

[This drawback to M. Guérin's method may be met and the plan improved upon by using chloralum wool in lieu of the common kind of wadding.—F. M. L.]

By this new method, it must be well understood, primary union is not to be expected; still, M. Guérin remarks that in a flap amputation, he had introduced cotton between the two flaps, and when he took off the first dressing he found that the cotton had slipped and the flaps become agglutinated.

In his first experiments M. Guérin hesitated to leave his patients without being dressed for a fortnight, the more so as they often complained, saying they were neglected. He has regretted having yielded too soon to their desires, and now for an amputation twenty days is an early term to uncover the wound. The first patients had been re-dressed in the wards which has the serious inconvenience of uselessly exposing the wound to contact with the vitiated air of the wards. The two first operation cases thus undressed showed symptoms of purulent infection one or two days after the exposing of the wound to the air. Now, M. Guérin has all the operation cases regularly removed to the theatre, and so undressed and re-dressed there in the midst of a comparatively pure atmosphere.

When the dressing is renewed it is good to wash the wound with a disinfectant, carbolic lotion, for example, but it is useless to irritate it by carefully detaching crusts, or even picking off too adherent cotton fibres. The skin is gently wiped, and the dressing renewed precisely as at first.

When one uncovers wounds dressed by cotton wadding, the difference of their aspect from that of wounds dressed by the ordinary methods is striking. The wound is rosy rather than red, it may even have a slightly greyish tint; on its surface one finds a layer of pus, much less considerable than one would suppose. Sometimes the pus remaining upon the skin about the wound has induced a little redness and desquamation, but nowhere any swelling or inflammatory redness; one is quite surprised to see a wound at first of considerable magnitude reduced to such small dimensions. We have seen undressed upon the 22nd of June a man, *æt* forty-five, whose thigh had been amputated upon the 1st of June, having been wounded a week previously. The pus accumulated in the wadding was abundant enough; it was a circular amputation case, the soft parts were a little insufficient, and the bone projected considerably. The surface of the wound was granulating. A rather large piece of cellular tissue which had mortified

was detached, and its prolonged contact with the wound had given rise to no accident. The result was excellent for a man at his age, assuredly intemperate. The case was a fracture of the tibia from a bullet.

It is not amputation wounds alone that present this remarkable appearance. A patient wounded on the 29th of May, was dressed before us on the 20th June; it was his second dressing done a little soon because the last had been imperfectly accomplished. He had on his arm and chest enormous patches of intertrigo which caused him suffering. His immense wound, inflicted by a shell, including the right shoulder and part of the back with broken bones and torn muscles did not cause him suffering and was visibly getting smaller.

With this dressing the patients do not suffer unless some trifling pain on the day after its application. Those whose upper limbs have been amputated walk about from the first day. A man whose shoulder had been disarticulated was in the garden from the fifth day out, and some whose lower limbs had been amputated walked with crutches before the first dressing had been changed. Some have suffered about the tenth or twelfth day, but it was mainly those who were very anxious to be dressed afresh; patients with difficulty accustom themselves to the idea that it is for their good that the dressings are not changed. As they are protected from any shock or jar, there is no inconvenience in their moving about.

At the time when Mr. Guérin commenced to apply this method nearly all the wounded were dying of complication, and no amputation case recovered. For three months here are the results obtained out of a considerable number of operations. Arranging the cases categorically, the results may be classed thus:—A First Series, April, includes six wounded; one a case of amputation of the thigh which was going on perfectly well and was carried off on the twenty-second day by secondary hæmorrhage; two subjects of re-section died of purulent infection after having had their dressings changed in the wards, and too soon; a very complicated case of re-section dead; finally, two cures, re-section of the radius and re-section of the acromioclavicular arch.

The Second or May Series was very important. Thirty-four amputation cases, thirty-five operations, fifteen deaths, nineteen cures. Those who died are thus classified: 1st, an amputation of the thigh, exhausted from loss of blood, died at the end of twelve hours; 2nd, an amputation of the thigh of a child, five months old; 3rd, an amputation of the arm, operation too long delayed, patient *æt* seventy-one, died; 4th, intra-malleolar, amputation too long delayed; 5th, amputation of the leg, tetanus; 6th, amputation of the arm, tetanus; 7th, intra-malleolar, amputation five days after the accident, previous purulent infection, and sudden death. Those first seven patients were evidently bound to succumb in spite of all possible care. Two cases of amputation of the thigh, two of the leg, one of the fore-arm probably died of purulent infection; we have not been able to obtain any precise information about them. Lastly, a case of amputation of the thigh, having undone the dressing, succumbed a few days after to purulent infection. A man, who had his leg amputated had the dressings changed on the second day on account of a hæmorrhage, and succumbed to purulent infection.

The examination of those cases of death teaches us that the greater number were attributable to special complications; that some, for instance, the two last, may, on the contrary, demonstrate the excellence of the procedure, and the danger there is in deviating from it. Moreover, the five cases about which we give no information, have no great value as against the method. In those days of confusion M. Guérin had the entire charge of the surgical wards of Hôpital St. Louis, his own as well as others'. He could not daily survey the dressings as is important to be done, and as he recommends; these cases belong to the extra patients who had undergone least inspection. Then we should take into account that upon first applying a

method there is always uncertainty and groping which interfere with the first results. Moreover, if it is legitimate to affirm that the method is an excellent one, it is unfair to require it to be infallible.

As to the cures here are the results :—19 successful : 6 amputations of the thigh, 5 amputations of the leg, 2 disarticulations of the shoulder, 4 amputations of the arm, 2 amputations of the fore-arm (one had both fore-arms amputated). All those patients were operated on six weeks ago, and are in excellent condition. All were traumatic amputations, some done on the first or second day, the majority on the sixth or eighth day, that is to say, under unfavourable circumstances. All eat and drink as much as possible ; the greater number walk about. A surgeon, a friend of mine, who accompanied me to St. Louis, was, like myself, astounded ; he had never seen in an hospital so many amputation patients alive and well. In a deplorable period those facts, much more favourable than one sees in ordinary times, are manifestly very striking, short as has been our examination of them ; necessarily we will have to study them anew. The method in fact is not confined to amputation wounds, and we might already cite several examples of cases in conservative surgery brought to a happy termination by this procedure. It is enough for us to call the attention of practitioners to this dressing, which along with its affording a security against purulent infection, &c, combines inappreciable advantages, such that we deeply regret it was not known before this war, many of whose victims it would have saved. It allows of the transport of patients from the very first day of operation. It suppresses with the daily manipulation the inevitable pains of the after treatment ; it renders unnecessary skilled assistants ; finally it constitutes a practice perfectly simple, always the same, and only demanding the employment of substances to be found everywhere or easily to be procured.

## Hospital Reports.

### KINGS' COLLEGE HOSPITAL.

*Polypus of the nose—Cyst on forehead—Fistula in ano  
—Excision of the elbow-joint—Fistula in perineo.*

(Under the care of PROFESSOR WOOD, F.R.S.)

ON the completion of the operation the Professor observed that the polypus of the nose was of the mucocellular variety, which was less common than the gelatinous form. It was his custom when operating on cases of this kind not only to remove the polypus itself entire, but also to remove a small piece of the turbinated bone to which it was attached. The gelatiniform variety was usually found to be attached to the nasal septum.

The cyst on the forehead Professor Wood removed by making a horizontal incision so as to leave less scar, corresponding as it would with the furrows of the occipito-frontalis. He then stated that the tumour had probably reappeared on account of the sac not having been completely removed. When the sac cannot be dissected out whole, Professor Wood breaks it up and then stuffs the interior with lint and carbolised oil, and so makes it heal from the bottom.

The case of fistula in ano was an example of the simple external in a patient suffering from phthisis. For some years past it had been the Professor's practice to operate in all cases of phthisis not far advanced. In many cases very great improvement in the general health of the patient had resulted from operating, and moreover when it was remembered how great the depression, annoyance, and anxiety that this disease produced, it was a great point to know that the operation relieved

these mental symptoms, and, in a very great many cases, the constitutional also.

The history of the patient with diseased elbow-joint was as follows :—He had been operated upon before for gelatinous degeneration, and for a time, with good living, change of air, &c., he had done well. After a time however, he fell into bad health again, but with feeding up he in the hospital improved ; afterwards the hospital air began to affect him, and he was sent out. For some time past he has been on tonics. On his return finding several sinuses existed, and that there was evidence of the disease having returned, Professor Wood determined to operate, and, following a favourite practice of his, laid open all the sinuses, removed the diseased parts, and also a portion of healthy bone. The parts were then first well sponged with carbolic acid and chloride of zinc lotion, a strip of lint soaked in carbolic oil placed in the wound, and a splint and bandage applied. The Professor observed that in this instance he feared there would be a return of the disease as it affected every tissue—bone, muscle, nerves, and vessels. The reasons of his removing the healthy bone were—First, the proximal ends rubbed against one another ; and, secondly, because a short arm was as useful as a long one. The contrary rule, however, obtained in the knee-joint, as if the leg here were much shorter than its fellow the drag in the gait would be proportionately greater. The bone was shown to the class, which was red and bleeding.

The case of the perineal fistula communicating with the bladder was caused by a severe fracture of the pelvis. The man was a miner. Mr. Wood brought away several pieces of diseased bone, and tied a catheter in such a manner as to leave it in the bladder in order that the urine might pass through it and so heal the fistula.

#### *Removal of tumour from knee.*

(Under the care of H. SMITH.)

Mr. Smith made a longitudinal incision about three inches long over the patella and carefully dissected out the tumour. The part was then well sponged, one or two small arteries twisted, water dressing applied, and a small splint placed behind the joint.

Mr. Smith then narrated the history of the case which was as follows : The girl had had originally a housemaid's knee which had been imperfectly cured and the bursa degenerated into a fibroid tumour. The class would notice that in cutting into it there was a central oval hole containing a quantity of soft degenerated tissue like lemon seeds, and this was the pathological answer they would be expected to give at the College of Surgeons in connection with the housemaid's knee when asked.

#### Animal Vaccination.

THE House-Physician, New York Dispensary, Dr. Frank P. Foster (*Medical Gazette*), considers the following propositions as well established :

1. Vaccination with bovine virus is at least as successful as that with humanised virus, and in our experience it has been more so. 2. There does not appear any valid reason for looking upon vaccinations with lymph procured from a succession of bovine inoculations are inferior, in the protection conferred against small-pox, to those with humanised virus, or with virus direct from cases of spontaneous cow-pock. On the contrary, in the case of the inoculated bovine disease, we can always be sure as to the precise period of the disease, and consequently, in taking lymph, can choose the time when it is most energetic, whereas we can seldom or never assign a precise date to the origin of a spontaneous case, and, indeed, must very rarely have an opportunity of seeing such a case until after the proper time for taking lymph has passed. 3. Vaccination with bovine virus certainly does not entail a risk of any greater degree of inflammation than is commonly met with in the use of the humanised stock. 4. Animal vaccination enables a

careful vaccinator to be *positively certain* that he runs no risk of unwittingly conveying syphilis in vaccination. 5. The amount of vaccinal efflorescence considered necessary to constitute an effectual prophylactic against small-pox is, with bovine virus, attainable with a decidedly decreased amount of traumatism. 6. As is now generally admitted, animal vaccination is a great addition to our sources of vaccine, and furnishes a safe-guard against 'vaccine panics.' On this account alone, if on no other, it should be steadily maintained.

### OBSCENE QUACKS.

THE universal difficulty which impedes all philanthropic movements seems to be the impossibility of inducing the public to believe in and appreciate the full gravity of the grievance for the redress of which the philanthropist pleads. When the public are told of the misery, squalor, and starvation of the very poor, or the cruelty, crime, and ruin involved in the frequency of drunkenness, they fail to respond to the representation; not because they are careless as to the sufferings or well-being of their fellow-creatures, but because they have an insufficient belief in the real truth of the statements, or because they regard them as the normal condition of things.

Those who have waged war against the trade of the obscene quacks, have felt these disabilities with greater force, because the subject is one of which the public have no personal knowledge whatever, and the nature of which involves it in secrecy. In spite of the expositions which have been made of the scandalous robbery carried on by the obscene quacks, the public at large does not even remotely suspect the enormity of the evil. Nay! even the Medical-Profession are perfectly innocent of the real extent of this system of fraud. The quacks themselves, and a very few other persons, are the only community who really know how vast and how wicked is the system; and this because the secrecy of the process begets an aversion to publicity on the part of the victim, who will rather suffer silently in mind, health, and pocket, than

unfold the narrative of which he has so much cause to be ashamed to a friend or a medical man.

We are prompted to these remarks by the tenor of a letter which has fallen into our hands, and which we give *in extenso*, as a narrative of the characteristic career of an unfortunate dupe. It is addressed to Messrs. Baillière, Tindall, and Co., the publishers of Mr. Courtenay's well-known exposure of "Quacks and Quackery":—

"TO MESSRS. BAILLIÈRE.

"Having received your pamphlet on 'Quackery' and read it, I feel very much interested with it, and cannot thank the author too highly for the advice therein given. Having been a sufferer from spermatorrhœa, with emissions, myself for five or six years. I have been duped to a great extent, but not so bad as some—probably out of £90 or £100. I suppose it would have been worse had I been better off. Smith, of Burton crescent, got £4 or £5 out of me, and did me no good. I received a pamphlet a little while ago, purporting to come from Stroud and Co., 20 Exeter street, Strand, W.C., entitled, 'Nature's Remedy.' I think this is in some way connected with Smith, of Burton crescent.

"I then saw an advertisement in a newspaper of one Dr. Watson, of the Lock Hospital, London. I got a curative appliance from him, some medicine, and a lotion. He fleeced me to the extent of £8 or £10, I believe, but did me no good.

"I was now so weak and nerveless that I thought I would try some one else.

"There was one, Dr. Culverwell, of London, about this time visiting Bristol professionally. I applied to him, and paid him £10 or £12. He cauterised me and made me worse.

"I now left him and tried a surgeon; he did no good—probably not acquainted with such cases.

"I now saw an advertisement, entitled 'Nervous Debility cured without the aid of quacks; apply to Secretary, Institute of Anatomy, 44 Great Charles street, Birmingham.' I had one of the pamphlets, and from what I read therein, I learned that no one else could cure these cases. So I took train and rode to the above place, about 100 miles. I took a small vial of my urine with me.

"When I came to the place, I was introduced to Dr. John Hunter, (*this fellow nearly frightened me to death*), who on examining me, said my case was an exceedingly bad one. He said my testicles and the cords leading from them was in a terribly relaxed condition. He said the cords that conveys the seed had all but disappeared, he then examined my urine, was away about ten minutes for this, when he came back he said mine was an unfortunate case, says he, the semen runs away with the urine just as it is formed from the blood, without entering the seminal vessels at all, and without any formation. He said he thought my case hopeless. I then told him if that was the case I had better not spend more money on it. He then said with care and following up his medicine and advice I may recover. He then wanted £10 for medicine, but I had not that sum at my disposal, so I agreed to pay his fee of one guinea and £6 for a case of medicine—twelve small bottles—one bottle would last about a week; but that was not the worst of it, it did me no good. I took that lot, and had two more £6 cases, making £19-worth in all, without the least benefit. My expenses in going to Birmingham and back must have been another £1, making £20. I enclose one of his letters.

"I now received a pamphlet from one, Monsier Duval, patent medicine agent, 13 Newmarket street, Birmingham, saying he was agent for the sale of a medicine called the new French remedy; so I have had £6-worth of this man's nostrums; I am taking of it now, but I shall not have any more of him, as it does no good. I think he has some connection with Dr. Hunter, as he says at the end of the pamphlet: 'Any persons in need of professional advice, apply to Dr. Hunter, 44 Great Charles street, Birmingham, who has been in practice thirty years, and may be fully relied on.'

"Now, if you would inform me where I may meet with a honest and straightforward surgeon or physician, I should very much thank you. I want one as will work cheap and in a short time.

"Through this complaint and the harm done me by the quacks I was obliged to give up business about two years ago. I was then in the farming line of business. I was so weak, both mentally and bodily, that I could not work nor carry on anything at all. I reckon this loss at £150, which, added on to £100 for medical advice, makes a large sum.

"I am now like the dove from Noah's ark, which had nowhere to rest her foot, not knowing who to apply to. Do you think there is any doctor in Bristol that can successfully treat my complaint? I am afraid of the London ones now. I wish you would let me know by return of post. I enclose three stamps for return post. I apologise for taking up your valuable time.

"Yours very truly,  
"J. G."

"P. S.—Is it any use to try a homeopathic doctor?"

"44 Great Charles street, Birmingham,  
"Oct. 14, 1870.

"DEAR SIR,—We are not surprised to hear you do not feel so much benefitted by this time as you anticipated; until the loss of semen in the urine is entirely checked, and sufficient time has elapsed for the seed to become infused in the nervous system, you will not feel benefitted by the remedies; but by persevering and following out the entire course of treatment, we have not the least doubt of being able to satisfactory effect your restoration. The escape of seed in the urine we feel no doubt is decreasing, and has the power of retention is gained you will improve. We informed you at the onset that it would take some time to effect your restoration, and that the case would be expensive; we should be sorry for you to suppose that you were throwing your money away, and it would be dishonourable of us to induce you to expend your money, unless we felt quite certain we could effect your recovery. The emissions are generally more frequent has the parts begin to act, and continue until the relaxed and irritable vessels become healthy. You had better send for another course of treatment, which we shall now change, and prepare to have a more direct action on the seminal vessels; and we may add we are quite certain we can effect your recovery, and fit you for marriage if you continue to persevere a sufficient length of time.

"Yours faithfully,  
"H. W. HUNTER."

Without moralising further on this subject, we pass to the consideration of the remedy for this hidden and villainous system. Without doubt the evil is worthy of the labour of extermination, for the extent of its ramifications and the number of its victims are incredible. We venture to surmise that every reader of these words has within his acquaintance or practice some unfortunate man who is being driven to the verge of lunacy or suicide by the cleverly worded insinuations of these quacks, and yet does not consult his nearest friend; and once immersed in the web of these rascals, struggles helplessly. It seems to us that the duty of stamping out this infamous traffic belongs to no part of the community so properly as to our Profession. We know not only somewhat of its extent, but we know how to invite the confidence of the victims, and in virtue of our scientific qualifications we can speak with authority.

The method of action would be simple and efficacious. Even if we did no more than receive confidentially the communications of victims like the writer of this letter, and afford them the advice which he longs for and seeks elsewhere in vain, we should have effected the major part of the object to be desired.

We earnestly suggest the formation of an Association for the Suppression of Obscene Quackery, with this object, and should such an organisation ever exist, we can promise them that their greatest difficulty will be the multitude of their consultants and an overwhelming flood of evidence, which will enable them to deal shortly, sharply, and decisively with the harpies engaged in such practices.

#### MEDICAL REPORT OF THE PRIVY COUNCIL.

WE have received with pleasure the Report of the Medical Officer of the Privy Council, and are glad that we

have thus furnished to us the opportunity of recurring to some of the points we have previously alluded to, as well as some others we had passed over. The Report is a small one this year, but none the less worthy of attention. Its price is, in fact, only fourpence halfpenny, which induced us the more readily to comment on the fact of our not having received it. Publications of this description need to be widely circulated, and there is no medium so useful as that of the Press. Quite a number of our own correspondents make enquiries about the various Blue books relating to sanitary matters, and we are desirous of keeping our reader *au courant* with all that transpires. Only last week, for example, we commented at length on the memorandum respecting hospitals for contagious diseases, because we were inundated with enquiries. It is to be hoped, therefore, that all medical journals may be regularly furnished with all public documents relating to sanitary matters; since, by directing attention to them, they only strengthen the hands of the medical department. If we have been sometimes compelled to differ with the views enunciated in them, we trust we have penned no criticism which the authorities should not be pleased to consider. It is free and full discussion that alone can mature the grain which has been so abundantly sown by the Privy Council. For this reason, among many others, we should be glad to see these Blue books circulated far more widely, and the small minutes and memoranda put in the hands of all medical men who may be likely to wish to refer them.

It is, no doubt, a difficult thing to meet this, but the department has overcome much greater difficulties. It would, of course, be useless to sow these documents broadcast over the land, inasmuch as they would only pass with hosts of others to the waste-paper basket. Perhaps, however, some notice might be issued that any member of the profession could receive copies on application. This would secure the object and prevent waste. We commend the notion to Mr. Simon, whose practical mind will probably at once, by this means or some other, secure the object sought.

We now turn from the Report itself, to Dr. Burdon Sanderson's appended paper "On Microzymes." Few subjects are just now of wider interest, and Dr. Sanderson's ability for these investigations is of the highest order. Still, we do not feel satisfied about his conclusions, and they lead to such results that so far as they can be fairly placed before the non-professional world, we are half afraid they will come to be regarded as unpractical. What with microzymes, bacteria, and other microscopic appearances, to say nothing of chemical impurities culminating in that—"previous sewage contamination"—in which so few practical chemists believe, it really would seem as if we are soon to be condemned to the old penalty and find

"Water, water everywhere, but not a drop to drink."

Let us hope, however, for a better fate, and find courage to look at some of the other bearings of Dr. Sanderson's investigations. We note then, that they are quite at variance with the views of Hallier, who considered the contagion of zymotic diseases originated in fungi. Dr. Sanderson believes that his experiments show there is a great difference in the origin and growth of fungi and microzymes. These solid gelatinous particles of the 1-20,000 of an inch diameter, do not pass through an animal membrane, as shown by Chaveau and others, and now Dr. Sanderson shows that they do not develop in

certain super-heated test liquids, although fungi may be fully developed. Here, then, is a liquid—super-heated, it is true, but that matters not, as it is used for both substances under investigation—in which fungi readily grow, but microzymes do not.

Then, on the other hand, we are told that fungi are not developed, notwithstanding the presence of microzymes in the same liquid in which they appear readily when air has access, but microzymes are absent. A drop of distilled water suffices to introduce them, as does contact with a solid like glass, unless it be first super-heated; but access of air alone does not introduce them. Hence, it is concluded that these microzymes exist in water, or attached to the surfaces of solids but do not exist in the air. In the distilled water, probably they come from the vessels in which it has been placed. The fact of microzymes being thus readily found in Pasteur's boiled solution, after contamination from external sources will, no doubt, be picked up by those engaged in the controversy on "Spontaneous Generation." We cannot stay to consider this, but pass on to report that Professor Tyndall has assisted Dr. Sanderson, by subjecting his liquids to the electric beam. Water obtained from a block of ice, almost of optional purity contained microzymes, and from the experiments made, it is at present impossible to say how minute they may be. Not only so, but we are met with other difficulties—such as the extreme difficulty of avoiding contamination. For this reason we do not look to this investigation as likely to give a list of "the zymotic power" of any sample of water. But if it shows that fungi may be excluded from future investigations into contagion, it is at least a step gained.

We are glad to get rid of fungi, still we must not put microzymes in their place, for we have no evidence to show that these gelatinous particles found in decomposing fluids, are identical with similar particles found in the fluids of contagious diseases.

Further, Dr. Sanderson cannot confirm the statements of Béchaugé and Hallier, that such particles are to be found in the fluids of human beings in health, or suffering from zymotic diseases.

He has passed blood and other fluids into test solutions with the same precautions as in other cases, without finding that they contaminate—as even distilled water will. Such being the case, we ought at present to hear no more of the notion that our structures, even in health, swarm with microzymes, and that a slight increase in their number is a sufficient explanation of zymotic diseases.

Dr. Sanderson has done good service in tracking this notion home, and his future investigations promise much. We thank him for his work, and the Medical Department of the Privy Council, for rendering it public property.

## Notes on Current Topics.

### The Government and the Profession.

WE must not give up the contest because the officials have gone for their holidays. The Director-General of the Medical Department of the Army is a member of our Profession. He cannot have failed to note the scandalous ill-treatment of Drs. Wyatt and Gordon. We wonder whether they look to him for redress. Certain it is that

other members of the service are being influenced by this treatment, and the whole Profession watches to see whether the head of the department will resent the insult offered to the Profession, through the men, we presume, he selected for an arduous post.

### The Cholera.

THE correspondent of the *Pall Mall Gazette* at the Hague writes:—

It is officially stated that at the Helder (Nieuwe Diep) a case of Asiatic cholera has occurred with a fatal result. The carelessness of our Government is most scandalous. Steamers and other vessels coming from Königsberg were allowed to enter the port without undergoing quarantine, and thence to proceed to Amsterdam. There is a general shipping trade between Nieuwe Diep and London.

A Prussian correspondent of the *Times* writes from Berlin on August 31:—

During the last few days fatal cholera cases have occurred at Dantzic, Elbing, Altona, Coblenz, Leipsic, and Vienna. In other words, the shores of the Baltic and the North Sea, the banks of the Rhine and Danube, and the centre of Germany have been simultaneously visited. In addition to the localities just touched by it, the scourge continues to rage at Königsberg and in the neighbouring districts of East Prussia. At Königsberg about 140 are seized daily, of whom one-third succumb. On August 26th the sum total of all those in Moscow seized since the beginning of the epidemic (March 13th) was 5,052. Of these 2,340 had recovered, and 2,354 were dead. A comparison of these last figures with those recorded in the third week of August proves that the mortality, which at one time exceeded half the number of cases, has latterly considerably diminished.

### Killed by a Wasp.

THE newspapers relate the story of a gentleman who died from the sting of a wasp in the throat. He seems to have swallowed the venomous insect, unawares, when drinking. It is known how great a swelling takes place from wasp stings in any loose tissue, and we can, therefore, readily understand how the victim might perish from cedema glottidis thus brought on. Such a consequence of the sting might be fatal before professional aid could arrive, and even when present a surgeon might not be prepared to perform such an operation as might save the life of the patient.

### Pharmaceutical Reform in America.

TILL very recently the druggists' and apothecaries of New York have been uncontrolled by any state regulations. Mistakes in dispensing have been very common, and deaths from ignorance on the part of chemists pretty frequent. In March last the legislature passed an Act with a view to meet these evils by the establishment of a Board of Examiners, who will license for the future all druggists and their clerks, after they shall have passed a satisfactory examination. The provisions of the Act were to take effect six months after the board was organised, and they are intended to secure the infliction of a fine of not more than 500 dollars upon, or the punishment by an imprisonment of a term not exceeding six months of, any person who shall act as a pharmacist without the license of the board. Both fine and imprisonment in some cases may be inflicted. The Board has been appointed and has got to work, but its doings at once met with decided hostility, especially from the druggists hold-

ing diplomas from the New York College of Pharmacy, which college asked that its diploma should entitle the holder to the state license without further examination. However this point was not conceded, and the disappointed druggists and others are now presenting themselves to be examined. About a third of the candidates fail to pass; and the havoc and consternation amongst the chemists may be readily imagined from a knowledge of this fact. There are about 430 or more druggists, and 1,300 "Druggists' clerks," in New York, who must, before practising as such, present themselves for examination before the State Board. It is believed that the new law will quickly raise the status of the pharmacist in New York, and give additional security to the public in the matter of drugs and dispensing.

#### How to Cure Disease.

DR. C. B. HALL, of Toronto, writes on "Consumption" in the *Canada Lancet*, and thinks that treatment must be chemical. He expects the good derived from cod-liver oil will be equalled by any fat properly given, and he says we must use an alkali with it.

This is his favourite formula:—

|                      |                  |
|----------------------|------------------|
| R—Bntyrin,           | oz. ij. drs. vj. |
| Vitell ovi,          | No. j.           |
| Pepsine,             | drs. ij.         |
| Soda bi-carb.,       | drs. iv.         |
| „ phosphat.,         | drs. iv.         |
| Theriaca (molasses), | oz. iij.         |
| Aq. flora aurant,    | oz. j.           |
| Syr. tolu,           | oz. iv.          |
| Aq. destill,         | ad. oj.—M.       |

In other diseases Dr. Hall professes to have arrived at certainty. Thus he tells us to alkalise the blood and pneumonia is arrested, so that liq. potassæ is specific. And diabetes he finds as easy to control.

In this disease the whole process is chemical; the nature and abnormal change is chemical; the prevention and cure alike act by chemical laws. Starch is given for food. Sugar is found in the excrements. In the cure, sugar is converted into the most important and useful agent in the animal economy. In each and every process chemical tests unquestionably confirm, "or at least so prove it, that the probation bears no hinge nor loop, to hang a doubt on."

Happy Dr. Hall to see through and remove disease after this fashion. Oh! for such faith!

#### General Medical Council.

A RECENT Blue book contains a statement that gives additional force to the arguments so fully pushed home a year or two ago by Dr. Prosser James. That gentleman based a large part of his project of medical reform on the narrowness of the existing Medical Council. The constituency he sought to enlarge is now officially reported to be as follows:—

*London*: College of Physicians, 235 voters; College of Surgeons, 24; Apothecaries' Society, 24; University of London, 36; total, 319. *Scotland*: College of Physicians, Edinburgh, 61 voters; College of Surgeons, Edinburgh, 250; University of Edinburgh, 34; Faculty of Physicians and Surgeons, Glasgow, 110; University of Glasgow, 25; University of Aberdeen, 22; University of St. Andrews, 14; total, 506. *Ireland*: College of Physicians, 47 voters; College of Surgeons, 21; Apothecaries' Hall, 35; University of Dublin, 8; Queen's University, 25; total, 136.

When we reflect that the actual voters in those bodies

that admit a considerable number are merely nominal, we cannot but feel that the evil is monstrous, and must form the subject of further agitation.

#### Supposed Asiatic Cholera at Walton.

At the meeting of the Walton Local Board, it was stated by Dr. Grattan, one of the members of the board, that there was, a few yards from the board-room, a case of cholera which he had no doubt was one of the Asiatic type. The patient had been a soldier in India, and whilst there had been attacked with Asiatic cholera. He (the patient) was confident that this was the same complaint. Dr. Grattan was called to him early on Sunday morning, and owing to the great prostration attending the case he had no doubt of the character of the malady. The patient was in a fair way of recovery.

#### Death of a Medical Man in Birkenhead.

AN inquest was held last week touching the death of Mr. James Douglas Murray, twenty-three years of age, which occurred on Tuesday night, at the house of Mrs. Craig, widow of the late Mr. Craig, surgeon, whose practice was continued by Mr. Murray. The deceased was the son of Mr. Andrew Murray, naval surgeon, attached to H.M. Training-ship *Eagle*, stationed in the West Float at Birkenhead. Miss Ann Craig, sister-in-law to Mrs. Craig, said the deceased, Mr. Murray, succeeded to the late Mr. Craig's practice as a surgeon. She believed his general health was good. Witness had not seen him since Monday, when he seemed as well as usual. On Tuesday, about a quarter to five o'clock, two people wanted to see him professionally, and she sent her niece (the previous witness) to tell him. The little girl returned and said Mr. Murray was asleep, and she could not wake him. Witness then went up, and also went into the room, and supposing him to be asleep shook him. As he remained motionless, she thought he had fainted, and feeling his forehead found that while the front was warm the temples were quite cold. Dr. Lambert stated that he was not in a position to assign any cause for the death. He was sent for, but when he came the young man was dead. He was a healthy young man, and enjoyed good spirits. Witness heard that about twelve months ago he had a fit, but could not speak of this from personal knowledge. At present he was not in a position to assign any cause of death. The Coroner said they had found two bottles in the room. One bottle contained prussic acid, and the smell was still strong in the bottle, for he (the Coroner) smelt it when he was viewing the body. It would not be satisfactory for them to close the inquest without knowing the cause of the death, and that could only be done by Dr. Lambert making a *post-mortem* examination of the body.

#### Dr. Jaccoud on Sequelæ of Measles.

LARYNGITIS stridulus is not so dangerous as was once supposed, if only the patients be left alone. Diphtheria is sometimes noticed in the period of desquamation, sometimes it commences on the posterior part of the throat and nasal fossæ, sometimes it proceeds from below upwards. It is almost always fatal. At the same epoch in the history of measles, we may observe diarrhœa, and this carries of many children in some of the epidemics. Very often children present evidences of scrofula after

measles; chronic ophthalmia, conjunctivæ, granulations, keratitis, or otorrhœa with catarrh of the nasal fossæ. Gangrene of the mouth and vulva is sometimes seen, capillary catarrh, emphysema, œdema, and tuberculisation of the lungs, occur after measles. Phthisis is always more common after epidemics of measles. M. Jaccoud insists on the daily inspection of the mouth in children with measles, since gangrene comes on insidiously by little excoriations. Fuming nitro-hydrochloric acid should at once be used, or the actual cautery. Epistaxis is not uncommon in measles, and are well treated by injecting water as warm as the patient can bear, whilst mineral acid lemonade is given interiorly, fifteen or twenty drops of hydrochloric acid to the litre of water.

### The Royal Orthopædic Hospital.

THERE has been a great explosion at the Royal Orthopædic Hospital, in Oxford street, concerning the death of some children from diphtheria; and the committee have been brought before the bar of public opinion by some of the medical officers. From what we hear, however, many of the medical staff of that institution deeply regret this "washing of dirty linen out of doors," and think that some of their colleagues are too fond of getting in a passion for nothing.

In many public institutions there seems to be one person who desires to exclaim with Louis the XVI., "*L'état c'est moi*," and we hear that such a gentleman exists also in that institution; and that the neglect alleged to have taken place must be taken *cum grano salis*. As a general rule, it certainly is better not to bring such questions into the vulgar gaze of idle newspaper critics, who know nothing about it, until the committee has been appealed to.

### The Contagious Diseases Act.

THE *Shield* of September 9th contains a letter from Dr. Taylor, of Nottingham, who complains of the conduct of the Council of the British Association at Plymouth, in allowing him to travel a very great distance to Plymouth for the purpose of reading a paper on the Contagious Diseases Acts at the meeting in August, under a promise that he was to be allowed to do so, and then at the last moment denying him this opportunity on the legal pretext that his paper had not been sent in exactly in time. We should like to hear the explanation offered by Dr. A. P. Stewart and others of this seeming want of courtesy to Dr. Taylor. THE MEDICAL PRESS AND CIRCULAR has always adopted the motto of *Audi alteram partem*.

### Mercurial Lotions.

A VERY unfortunate case of fatal mercurial poisoning through the use of a very strong mercurial lotion of corrosive sublimate (60 grains to the ounce) has just been recorded in the daily papers. As a general rule, it would be as well for all of us to remember that such cases have been from time to time recorded; and then we shall be more cautious in our use of mercury. If, indeed, it were clearly proved that mercurial lotions were *absolutely* necessary for the cure of ringworm, we should, of course, have to take our chance of fatal consequences; but when we know that blistering fluid will cure this affection probably more rapidly than any other remedy, it seems needless to have recourse to very strong lotions of cor-

rosive sublimate. It would really be quite a blessing to mankind were it possible to get rid of the use of mercury as an internal remedy, and as a remedy for external application. There is, doubtless, far less of the metal used now than formerly, but it is still too popular in syphilis and iritis to make it likely to disappear from practice. Meanwhile, we should be ever watchful, and see that such cases as that alluded to sink deeply into our minds.

### An Advocate for Chloralum.

THE worthy Deputy-Coroner for Central Middlesex, Dr. Hardwicke, is certainly a most zealous advocate for the new disinfectant. In his official capacity he held two inquests on Saturday last, at each of which he was eloquent in its praise. The one was a case of accidental poisoning by the wife of a surgeon, who swallowed carbolic acid in her thirst for spirits. To prevent cases of this description, remarked the coroner, "use chloralum; it is perfectly harmless, more efficient, and cheaper. Its use would entirely do away with poisonous disinfectants." The other inquest was upon the daughter of a labourer, who died from effusion of serum on the brain, her death being accelerated by the foul air of the place in which her parents lived. The summing up was, as in the preceding case, a splendid advertisement for the Chloralum Company. "Compel the officers to purify the air by putting chloralum in the drains, gully-holes, &c." At the day of reckoning we hope the company will not overlook the part the doctor has played towards insuring good dividends for their investments.

### Health of Dublin.

IN the Dublin Registration District, the births registered during the week ending 26th August, amounted to 191. The average number in the corresponding week of the years 1864 to 1870 inclusive, was 164. The deaths registered during the week were 128. The average number in the corresponding week of the previous seven years was 143. Nine deaths resulted from fever, viz.:—2 from typhus, 4 from typhoid, and 3 from simple continued fever. Four deaths from scarlet fever, and 2 from diphtheria were registered. Diarrhœa caused 10 deaths. The Registrar of No. 2 South City District (High street) remarks:—"Diarrhœa is very prevalent in this district." Thirteen children died from convulsions. Six deaths were ascribed to bronchitis, and 4 to pneumonia. Disease of the heart proved fatal in 4 instances, and aneurism in 2. Two deaths were attributed to liver disease. Seventeen deaths resulted from phthisis, 3 from scrofula, 4 from hydrocephalus, and 1 from mesenteric disease.

### Abolition of Sick-Mess Savings.

IN accordance with suggestions made by Sir Alexander Armstrong, K.C.B., the Medical Director-General of the Navy, it is in contemplation by the Admiralty to abolish the present system of "sick-mess savings" on board Her Majesty's ships, and in lieu thereof to authorise the surgeon to draw upon the paymaster for a certain sum periodically. The *United Service Gazette* says that, as the desirability or otherwise of the abolition of the present system will depend upon the amount allowed to be drawn by the medical officers of the respective ships, it is to be hoped

that in estimating this sum a fair and liberal average of the present mess savings will be taken, according to the stations on which ships have been serving, and not on each class in commission only.

### Vaccination in Manchester.

At the usual weekly meeting of the Manchester Board of Guardians, the Clerk reported that the evil arising from the delay consequent on the existing arrangements, by which returns of defaulters are made only once in six months, is again apparent in the present occasion, there being no fewer than 615 of the defaulters, or 35 per cent. of the whole number reported, whom the officers have been unable to find at the addresses given when the births of the children were registered. The house-to-house inquiry has resulted, as shown by the official reports, in the discovery of 2,094 unvaccinated children in the township, including the cases reported by the relief officers who have taken part in the inquiry. But as the compulsory powers conferred upon boards of guardians by the Vaccination Act are confined to children between the ages of 3 months and 14 years, and as 908 out of the number reported did not fall within these limits as to age (38 being above 14, and 870 under 3 months), there remained only 1,187 who could be dealt with by the guardians. It will be observed that the net result of the house-to-house visitation has been the discovery in the township of 1,187 unvaccinated children, who were of an age at which vaccination can be enforced. This result, showing as it does a percentage of only 0.68 upon the whole population, is more favourable than what was anticipated a few weeks since, and having regard to the defective provision made by the Act of 1867 for reporting defaulters, may be regarded as a proof that the law has been enforced wherever it has been found practicable to do so.

### Action of Heat on Protoplasmic Life.

THOSE investigators of germ-life who favour the theory of spontaneous generation have assumed that a temperature of 212° Fahr., or the boiling-point of the fluid which they experimented upon, was sufficient to destroy all protoplasmic life, and that the life they subsequently observed in these fluids was developed from non-living matter.

Mr. Crace Calvert has, therefore, made several series of experiments, in the hope that they might throw some light on the subject.

The first series was made with a sugar solution, the second with an infusion of hay, the third with solution of gelatine, and the fourth with water that had been in contact with putrid meat.

To carry out the experiments Mr. Calvert prepared a series of small tubes. The fluid to be operated upon was introduced into them, and left exposed to the atmosphere for sufficient length of time for germ-life to be largely developed. Each tube was then hermetically sealed. They were then placed in an oil-bath, and gradually heated to the required temperature, at which they were maintained for half an hour.

The results recorded by Mr. Calvert show that protoplasmic life is but slightly affected by a temperature of 212° F., and that, even at a temperature of 300° F., it is not entirely destroyed, excepting in the case of gelatine. In all the other fluids a temperature of 400° F., is necessary to completely destroy the life. These experiments,

therefore, clearly show that the life found by previous experimenters in fluids which have been submitted to heat was not due to heterogenesis, but to life which had remained in the fluids.

This important result corroborates those recorded in my previous paper, and proves that the spontaneous-generation theory is not yet by any means established.

### Ice-making Machine.

MESSRS. NASMYTH, WILSON, and Co., have lately made an ice-making machine on the principle of the patent of M. Mignot, of Paris, and the fact of the low temperature of compressed air when allowed to dilate. The machine forces this compressed atmosphere under and all round metal moulds, filled with water, which are placed in a cylindrical compartment, which communicates with an air-tight box. The difficulties which have formerly prevented the adoption of this method are, it is said, overcome by means of injecting cold water with the air while it is being compressed. The machine, working at a pressure of 60 lbs. to the square inch, produces 50 lbs. of ice in an hour. There is no expense for materials by this process, as atmospheric air and cold water are the only essential requirements of this ice-making machine.

### The Census.

THE *Presse Médicale Belge*, of August 20, states that the late Census of Great Britain, gives 31,817,108 persons, of whom 16,267,837 are women, and only 15,549,291 are men. Previous censuses showed an excess of women which is not extraordinary when so many men are employed as sailors, or affected with the spirit of colonisation. What appears most clearly from the above cyphers is, that the increase of population on the other side of the Manche is rapid, and that in the country where Malthusianism took birth as a doctrine, it is not yet practised. That is, on the contrary, the great sore which would depeople the United States, were the effects not counterbalanced in part by a numerous emigration of Europeans.

### Stimulants in Workhouses.

THE extraordinary consumption of stimulants in the West Derby Workhouse in Liverpool, is to be the subject of an enquiry for which a committee has been appointed. For the liquor of less than a thousand persons on an average, the guardians have paid thirteen hundred pounds within a year.

### Treatment of Hæmorrhagic Small-pox.

MR. JOHN AIKMAN, M.B., Assistant Medical Officer, Hampstead Small-pox Hospital, London, informs the *Glasgow Medical Journal* that, in the hæmorrhagic form of small-pox, he has observed the most beneficial results from the administration of two table-spoonfuls of the following mixture every three hours:—

℞ Liqueuris Strychnæ, ... ..  
℥k. Ferri Muriat, ... .. āā.ʒj.;  
Inf. Quassæ, ... .. ad. ʒviii. M.

On this the editor of the able *Quarterly* named, adds,—  
“The action of the strychnia, as a nerve tonic, is that which is chiefly sought; and as Mr. Aikman, as well as others of the medical attendants on small-pox in London,

are much impressed with its value, we insert this Memorandum, pending the production of detailed cases and statistics of results, which we hope to receive shortly."

### Portable Mixtures.

A NEW method of administering medicines has been proposed in Sweden, and has come into extensive use in France in consequence of the advantages which it possesses. It is the employment of gelatine as a vehicle, of which Professor Almen, of Upsala, is the initiator. Six grammes of gelatine are dissolved in warm water, and the desired medicine is added to the solution, which is then turned out on a glass plate to solidify, evaporate and dry. This mass which is about as thick as paper is then divided into squares of such size as to contain the proper dose of the medicine. A slight addition of glycerine makes this preparation tough and flexible as paper. Insoluble agents are added to the gelatine solution by a thick emulsion of gum or tragacanth.

Morphia, emetics, acetate of lead, sulphate of copper, extracts of opium and belladonna and powders of digitalis, hippo and camphor are thus easily kept ready in a portable form and administered when necessary.

### The Cost of War.

THE last war has cost the lives of 101 German doctors. Six died on the battle-field, sixty-six suffered from gunshot wounds, two were wounded in consequence of their own imprudence, and twenty-five died of various diseases, including eight of typhus and four of dysentery.

### Precautions against Cholera in London.

At a meeting of representatives of various districts abutting on the Thames, the Mayor of Gravesend in the chair, the following resolutions were agreed to :—

1. That this meeting of representatives from the various Boards and districts abutting on the Thames recognises the advisability of a joint action in appointing a sufficient staff of officers for the inspection of shipping, for the provision of the necessary hospital accommodation in cases of cholera, and for the disinfection of shipping and infected articles, under the recent Orders of Council.
2. That application be at once made to the Government for the use of one of her Majesty's ships, to be used as a hospital below Gravesend, for patients suffering from cholera on board ship.
3. That this meeting forms itself into a committee for taking the necessary action for the inspection of shipping on the River Thames, and to adopt such measures for the treatment of persons affected with cholera, and to prevent the spread of the disease, and to take such measures as may be deemed needful. Dr. C. Meymott Tidy is secretary.

DR. LYELL has published in the *Glasgow Quarterly Medical*, a case of partial displacement of the radius in a child. On examination the child's hand was fully prone, and the fore-arm semi-bent; but on examining the elbow joint Dr. Lyell could not detect any sensible displacement of its component bones. He took hold of the child's right hand in his own right, and the elbow joint with the left, placing his thumb over the head of the radius; then supinated the hand fully, at the same time extending the forearm. In the act of supination he could feel the head of

the radius give a slight jerk. On liberating her hand the child began to use her arm and returned to her play.

Dr. Lyell says, "This is one example out of many of this species of injury that have come under my observation, so that it cannot be by any means a very rare occurrence, yet of all the surgeons with whom I have conversed, Dr. Tannahill of this city is the only one who seems to have fallen in with it. Generally the accident has occurred with girls, uniformly under five years of age, and repeatedly in the same subject, for having once taken place there is a proclivity to return. In three different children I have seen it occur four or five different times. A fall on the side or sudden pull or twist of the arm is the usual cause of its production.

"Like Hey's accident to the knee joint, there seems some difficulty in defining the true nature of the displacement. Dislocation of the head of the radius was pointed out by Baron Bazer to be a commoner accident than had been previously admitted, particularly amongst children, but then he adds, the dislocation is always complete. Now, in this sort of injury, although the position of the arm, pronation, and semiflexion are the same, there is certainly no complete displacement backwards of the head of the bone, nor to the touch is there any sensible displacement. Yet that such is the case is evident from the slight snap or grating felt after the manipulation recommended, and the immediate restoration of the mobility and use of the limb. It seems to me that the radius somehow from over-supination catches on the adjacent ulna and is there retained. From the laxity of the ligaments in some children, this is permitted without their rupture.

"The derangement itself is not of a serious nature, and easily rectified when recognised, although I am not aware that it has been previously noticed in any surgical works. I have known one fall produce it, and another fall put it to rights again in a child liable to the accident, for in liability to recurrence, as I have stated, it is like Hey's knee, though frequently it occurs but once.

"Faith in bone-setters seems a settled portion of the popular creed in many parts of the country, and there can be little doubt that the treatment of such cases as this tends greatly to the confirmation of the popular faith, for in true dislocation the bone-setter is usually powerless for good especially in the elbow joint. It is better therefore that the surgeon should in all cases anticipate the bone-setter, and to this end I have not deemed it unnecessary to submit the foregoing to the profession."

THE recent severe cyclone which passed over St. Thomas's, killed upwards of fifty persons and wounded seriously eighty others. At Antigua eighty perished, and several hundreds were seriously wounded.

LATEST telegrams state that neither at Stettin nor at Danzig have any fresh cases of cholera been reported. At Kō nigsberg, on the 7th inst., 32 persons were taken ill, of whom 20 died; and at Elbing, on the 6th, four cases and two deaths occurred.

At an inquest held in London on Saturday last, Dr. Hardwicke, the coronor, remarked that he had been to see the body, and had likewise visited two other houses in Hat-in-tun yard, where the death occurred. He had at various times been in every part of the metropolis, but never saw anything to approach this place for filth and stenches; manure covered the staircase, and the stench arising from the closet was so great that it made him feel quite ill. Places like this were the birth-places of fever, cholera, and other contagious diseases, and were the cause of great loss of life, and entailed great ills on those who did not actually succumb to the pestilence.

IN Russia there is one doctor to every 17,800 inhabitants. In Prussia, one to every 3,100, in France to every 2,600, in Great Britain to every 2,500, in Italy to every 2,200, in Holstein to every 2,100, in Hamburg to every 1,230.

THE weekly mortality of Paris to Saturday last rose to 943. Of this number 42 were cases of dysentery, and 39 of typhoid fever. Dr. Decaisne reports that the latter is considerably increasing, not only in Paris, but in the departments, where it prevails in an epidemic form. There have been 40 deaths from cholera, 87 from diarrhœa, and 2 from cholera.

THE next examination for the London Apothecaries' Annual Distribution of Prizes in Materia Medica and Pharmaceutical Chemistry will be held on Wednesday, the 18th, and Friday, the 20th of October, at 10 a.m.

The Prizes consist of a Gold Medal and a Silver Medal with a book.

DR. MARSHALL, in a note to the *Preston Herald*, denies the statement about the Lancashire fasting girl, who is his patient. He says the parents are respectable, and grieved at the public notice of the case. The child does eat, but takes only a small amount of food—having been confined to her bed many weeks. We are glad Dr. Marshall has put an end to the absurd sensational reports.

THE following bequests to Medical charities are announced: By the will of Mrs. Morrison, of Snaresbrook, Essex, the Victoria Park Hospital for Diseases of the Chest and the Dover Infirmary each received £500.—The will of Giles Loder, Esq., merchant, of 1 Clarendon place, London, is proved under three millions—in which are bequests to the Salisbury Infirmary, £5,000; Christ's Hospital and the Asylum for Idiots, £2,000 each. The Orthopædic Hospital, Western General Infirmary, St. Mary's Hospital, Paddington, Royal Hospital for Incurables, Royal Medical Benevolent College, Western Hospital, Torquay, The Brompton Consumption and Cancer Hospitals each, £500.

## Literature.

### CHOLERA.\*

THIS bulky volume has been so long a time before us that we ought almost to apologise to the author for not noticing it before. The threatening of an invasion invests the subject with new interest, and naturally sends us to peruse the laborious work of an author who has not only watched the disease in India, but has had the opportunity of comparing his own experience with that of others. Like many other writers on cholera Mr. Macnamara offers us a theory. This we may briefly state thus:—

Cholera never originates *de novo*, but always spreads from person to person by means of the discharges finding their way into drinking water, and thus into the alimentary canal. But in order that it may induce its specific action on the walls of the intestinal canal this infecting matter must be in, what Mr. Macnamara calls, the vibronic stage of decom-

position. Nevertheless, no special influence in inducing cholera is attributed to the vibriones; their presence simply indicating that the organic matter in the water is passing through a certain stage of decomposition, during which process, it seems capable of imparting a similar action to the epithelium of the intestinal canal—a conversion of force. It is therefore only necessary that the organic matter of this particular stage of decomposition should find access to the intestinal canal, and undoubtedly it does so most frequently, by the contamination of the drinking water, but it is conceivable, that, if the dejecta of a cholera patient be allowed to dry, either on the floor of his room, or on his clothing, minute masses may become disengaged, and, floating in the air, attach themselves to the mucous membrane of the mouth and nose, and be swallowed with the saliva. The frequency with which washerwomen and the attendants upon the sick suffer is accounted for in this way by our author.

It will be seen at once that this hypothesis may be accepted by those who have committed themselves to the water theory while it essentially differs from them.

When the decomposition of the dejecta has passed beyond the vibronic stage cholera can no longer be propagated, and this is the reason why on a ship sailing from Calcutta the disease often breaks out in a few days and then subsides. Dry earth destroys the power of dejecta to propagate disease, but moisture, says Mr. Macnamara, restores it—a point that we suppose not a few will be ready to dispute.

The influence of winds has been exaggerated. The author tells us the disease will sometimes advance against the wind, but that it never travels faster than human beings. He, in fact, traces its progress always to human intercourse. As the stage of decomposition depends on heat and moisture so does the disease, and it is to their influence the author believes is due the variation as to outbreaks in different years. Thus we are once more referred to the weather as the great cause of the scourge.

Mr. Macnamara has carefully studied the morbid anatomy of the disease, and enters into a full description of the appearances he has met with on dissection. It will provoke Dr. Johnson to be told on the authority of numerous autopsies that anemia of the lungs is not to be found, except occasionally, as a single manifestation of a general deficiency of the blood, and that it is impossible to attribute it to spasm of the pulmonary capillaries. We think Dr. Johnson will feel bound to account for this—especially as in reference to treatment this Indian authority is equally opposed to him; for he says the eliminative plan is followed by great mortality, and that in his opinion he is supported by ninety per cent. of Indian practitioners.

Mr. Macnamara does not believe in fungi as will be seen from the following passage:—

“Even after protracted collapse I have examined the contents of the intestinal canal diligently for the appearance of mycelial threads or sporangia, and have absolutely failed, in numerous instances, in detecting any characteristic elements of the kind. They may exist there, but I should be sorry to have to define them, and much less to determine to what species they belong. Of this I feel confident, that they do not produce in the dejecta from cholera patients species differing from those which are grown in decomposing epithelium, and mucus from the intestines of human beings dying from other diseases. I have varied my observations bearing upon this point in every conceivable way, and although hoping, year after year, to discover a fungus peculiar to cholera, and thus settle much that was obscure in the etiology of the disease, I am reluctantly compelled to abandon my faith in the existence of any such growth.”

The prevention of the disease, if the author's hypothesis be true, resolves itself into providing pure water and insisting on quarantine. As to treatment opium and other as-

\*“A Treatise on Asiatic Cholera.” By C. Macnamara, Surgeon to the Calcutta Hospital. London: J. and A. Churchill.

tringents will check the discharge in the early stage. We are told that acids check the molecular changes in the epithelium of the alimentary canal, and therefore acid drinks should be given. Citric or dilute sulphuric acid are mentioned. No doubt lemon-juice would be more pleasant to some, but sulphuric acid has long had a reputation for both diarrhoea and cholera. It would therefore seem natural to prefer it.

The book before us contains a vast amount of material, and we hope this will be carefully digested by those who meditate writing on the subject.

## Correspondence.

### SOLDIER OR CIVILIAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Every medal has its obverse, the drawbacks, the objections to discipline and exile of a military career are well known. Now compare the life of a soldier with that of a civilian, contrast the healthy out-door employment of the one, with the arduous and frequently noxious trades of the latter; workmen in foundries exposed to the tremendous heat of furnaces; shopmen with puffy features, narrow chests, and lustreless eyes; clerks in banks and offices confined to sedentary occupation, stooping over desks and counters, and unable to obtain fair share of bodily exercise, often suffer from cramped wrists; the men working in coal pits deep down in the dark recesses of the earth, exposed to the risk of fire-damp, explosions, their bodies are cramped also; men in tin and copper mines, the vein of metal sometimes extending out to sea, and the loud roar of the Atlantic billows overhead distinctly heard by the poorly paid toilers; the sailor exposed to the fury of the wind and the waves, and the fisherman in spite of patient watching often on the verge of starvation. Dr. Lynter tells us all this, and the diseases workmen are liable to. Lead smelters, plumbers, painters, suffering from palsy, brain affection, and gout; miners, potters, masons, steel grinders, pin makers, wool-spinners, millers, snuffmakers inhaling fine, irritating dust, suffer from bronchitis, asthma, and phthisis; butchers exempt from the latter complaint, are prone to inflammatory diseases; Lucifer match makers, *ex luce lucellum*, in addition to threatened taxation, suffer from diseases of the jaw; brass melters of Birmingham have ague, and the hair of filers of brass turns (*à la Titmouse*) green; tailors working on the shop board on dark clothes in badly ventilated workshops, have defective sight; bakers and printers busy like owls at night, incline to phthisis; shoemakers and weavers in addition to republican ideas, frequently have disease of the stomach owing to constant pressure; and cabmen, coachmen, and engine drivers, exposed to a hurricane of air, and to wet exposure are addicted to rheumatism.

In all these occupations when men are worn out there is no pension, the charity of friends or the workhouse appears the alternative.

After all the soldier has many advantages sufficient to attract a good and healthy class of men.

I am Sir, your obedient servant,

FRANCIS R. HOGG, M.D., R.H.A.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I know a case where the refuse stuff from a starch factory is causing a great nuisance. The magistrates have not heretofore done anything effectual for its abatement, though the case has been several times before them.

Could you through the MEDICAL PRESS give me any information as to what should be done in the case? The "local authority" has mismanaged its case.

What is usually done in towns with the refuse of starch works? It contains the gluten of the wheat, and when this decomposes, it emits a most sickening smell. If this starch refuse be permitted to enter the town sewers without being changed in composition by the addition of some chemical agent, it will be strange intelligence to me.

I will feel most thankful for any information legal or

chemical, which you may publish in reply to this in the MEDICAL PRESS AND CIRCULAR.

I am a constant reader,

JUNIUS.

[If the case has been several times before the magistrates, we presume they were unable to deal effectually with it, for some such cause as want of sufficient evidence. If the nuisance cannot be abated under the provisions of the Public Act of 1866, you might proceed by indictment in the Queen's Bench, but before you do so, it would be well if you ascertained the reasons assigned by the magistrates for dismissing the case. Rice starch refuse is generally used for feeding pigs, and there is no good reason why it should be allowed to pass into the sewers.—ED. M.P. & C.]

### ALLOPATHY VERSUS HOMŒOPATHY AT SOUTHAMPTON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Guardians of the poor have at all times an unenviable duty to discharge, but, how unmeasurably added to when they have imposed on them work, the nature of which they are incapable of forming the slightest conception—whilst, in their ignorance, each and all will not fail to chatter as if they fully comprehended an intricate question—that of making proper medical provision for the really necessitous.

I intend my remarks for guardians in general, but more especially as applicable to those of Southampton. A young gentleman who was lauded for honestly declaring himself a homeopath, *simple and pure*, carried our shopkeepers by storm, assuring them that the paupers would be cured at a less cost, more quickly, and far more safely than by the old system.—Prodigious!

He produced testimonials from distinguished men who are unknown to fame as homœopaths, but should they be perverts ashamed of their colours—out with them! and let them be held up to the contempt they merit. I will endeavour to obtain, and forward to you their names for that purpose.

The homœopathic statistics, as contrasted with the allopathic, almost took away breathing power to hear them read. In the cholera epidemic of 1849, the only infinitesimal man who practised in Southampton, so far as I was aware, lost his patients and bolted. It was my misfortune to see some of them when they had reached a hopeless condition.

The proposer of the successful candidate boldly declared that he had qualified to practise by having passed the highest known standard of examination. Now, is it at all probable that a gentleman, occupied in selling coals, can be an authority on medical qualifications—especially since he appeared ignorant of the fact that the lowest of the nineteen Boards authorised to examine and license gentlemen to practise, would unhesitatingly reject every *simple* homeopath who ventured to present himself under his true colours in the event of their detecting his falsity and dishonesty?

When shall we be provided with a properly constituted Board of Health to appeal to in questions so essential to the welfare of the masses?

I am, Sir, yours faithfully,

EDWIN HEARNE, M.D.

Southampton, Sept. 8, 1871.

## OBITUARY.

### DEATH OF GEORGE DAVID MACLAREN.

DEPUTY Inspector-General of Hospitals and Fleets George David MacLaren died on Aug. 3, at Brockhurst, Gosport.

He entered the Navy, Dec. 23, 1828, on board the *Victory* as Assistant-Surgeon. He served on the East Indian station, and on the North American and West Indian station; promoted to the rank of Surgeon, Dec. 28, 1837. He was present at the bombardment and capture of St. Jean d'Acre, on Nov. 3, 1840, for which he received the war medal for Syria and Turkish medal. Attained the rank of Staff Surgeon in 1860; was raised to the rank of Deputy Inspector-General of Hospitals and Fleets on the retired List, Jan. 16, 1866, and was granted Greenwich Hospital pension, March 1866.

## ROBT. SHIPMAN, F.R.C.S.

THIS gentleman died on July 25, aged fifty-four. He was Surgeon to the Grantham district of the Great Northern Railway, and Surgeon of the second battalion of Lincolnshire Volunteer Rifles. He was formerly Surgeon to the Royal South Lincoln Militia. He was also a member of the Borough Corporation, an Alderman, and Justice of the Peace. His remains were followed to the grave by about forty gentlemen unconnected with his family, including the Mayor and most of the Corporation of Grantham.

## WILLIAM FAVELL, F.R.C.S., SHEFFIELD.

MR. FAVELL was admitted a member of the Royal College of Surgeons in 1821. His father, the late Mr. John Favell, was one of the surgeons to the Infirmary; his brother, the late Dr. Charles Favell, was one of the physicians; and his son, Mr. W. F. Favell, is now one of the surgeons connected with it. On entering upon his seventy-fifth year, he retired from the more active duties of his trying and laborious profession. A Sheffield paper says:—"Although the duties appertaining to a large family and a very extensive practice, prevented Mr. Favell from taking an active part in any of our public institutions or societies, few men were so universally esteemed in the sphere in which he moved, or won so entirely the confidence and admiration of a numerous circle of friends and patients. Careful and cautious in his treatment, clear in judgment, and kindly in manner, with always a genial turn of humour and sparkle of wit that made even his most melancholy visit to the sick-bed bring a ray of sunshine with it; his memory will long be cherished by those who knew him and reaped the benefit of his long experience and wise counsels. Although arrived at the advanced age of seventy-four, in appearance he was scarcely sixty, and his manners and conversation had all the freshness and vivacity of youth; while his erect figure, and handsome countenance will long dwell on the memory as a pleasant reminiscence, and a type of nature's true nobility."

## Medical News.

**Apothecaries' Hall of England.**—At a Court of Examiners, held on Thursday, the 7th instant, Messrs. Charles Raines, of the Hull School of Medicine, and William Rendall, Guy's Hospital, were admitted Licentiates of the Society of Apothecaries; and Messrs. Ambrose Lewis Davies, of St. Mary's Hospital, and Gilbert William Northey, of St. Thomas's Hospital, passed the primary professional examination.

**St. Thomas's Hospital, Albert Embankment, Westminster bridge, S.E.**—We are requested to state that this hospital is now open for the reception of patients.

**A New Siloam at a Highland Loch**—Dipping for the Cure of Disease.—A correspondent of the *Inverness Courier* gives a description of a strange scene which he says he witnessed at a loch in the district of Strathnaver, Sutherland. Dipping in this loch for the purpose of effecting extraordinary cures is stated to be a matter of periodical occurrence, and the 14th ult. appears to have been selected as immediately after the beginning of August in the old style. The hour was between midnight and one o'clock, and the scene was absurd and disgraceful beyond belief, though not without a touch of weird interest, imparted by the darkness of the night and the superstitious faith of the people. "The impotent, the halt, the lunatic, and the tender infant were all waiting about midnight for an immersion in the Lochmanur. The night was calm, the stars countless, and meteors were occasionally shooting about in all quarters of the heavens above. A streaky white belt could be observed in the remotest part of the firmament.

Yet with all this the night was dark—so dark that one could not recognise friend or foe but by close contact and speech. About fifty persons, all told, were present near one spot, and I believe other parts of the loch side were similarly occupied. About twelve stripped and walked into the loch, performing their ablutions three times. Those who were not able to act for themselves were assisted, some of them being led willingly and others by force, for there were cases of each kind. One young woman, strictly guarded, was an object of great pity. She raved in a distressing manner, repeating religious phrases, some of which were very earnest and pathetic. She prayed her guardians not to immerse her, saying that it was not a communion occasion, and asking if they could call this righteousness or faithfulness, or if they could compare the loch and its virtues to the right arm of Christ. No male, so far as I could see, denuded himself for a plunge. These gatherings take place twice a year, and are known far and near to such as put belief in the spell. But the climax of absurdity is in paying the loch in sterling coin.

**The Medical Staff of the Aldershot Field Force.**—The distribution of staff medical officers detailed for duty with the Army Corps and field hospitals of troops at Aldershot during the autumnal manoeuvres are as follows:—1st Division—P. M. O. Staff Surg-Major H. Kendall, M.D.; 1st Field Hospital, Staff Surg-Major F. Holton, M.B., in charge, Staff Assist-Surgs. W. Day and A. Sheddon, M.D.; 2nd Field Hospital, Staff Surg. R. Hungerford, in charge, Staff Assist-Surgs. J. W. Longheed and W. F. Burnett; 3rd Field Hospital, Staff Surg. J. R. Thomas, in charge, Staff Assist-Surgs. T. G. Bolster, M.D. and T. A. J. Cocksedge. 2nd Division—P. M. O. Surg-Major J. Sinclair, 33rd Regiment; 1st Field Hospital, Staff Surg. C. M. Miller, in charge, Staff Assist-Surgs. R. Spence and M. L. White; 2nd Field Hospital, Staff Surg. R. Watson, in charge, Staff Assist-Surgs. J. Y. Donaldson, M.D. and C. S. Wills; 3rd Field Hospital, Staff Surg. N. Ffolliott, in charge, Staff Assist-Surgs. C. M. Churchill, M.B. and J. H. Reynolds, M.B. 3rd Division—P. M. O. Surg-Major J. J. Clifford, 9th Lancers; 1st Field Hospital, Staff Surg. E. Y. Killitt, in charge, Staff Assist-Surgs. White and W. St. Martelli; 2nd Field Hospital, Staff Surg. W. Grenott, in charge, Staff Assist-Surgs. W. T. Martin, M.D. and T. J. P. Holmes, M.B.; 3rd Field Hospital, Staff Surg. G. Palatiano, M.D., in charge, Staff Assist-Surgs. W. Blake and C. Smith. The principal medical officers of divisions will have the entire management of all the medical arrangements of their divisions, subject to the instructions of the General commanding them, or of the Inspector-General of Hospitals, R. Lawson; and the officers and subordinates connected with the field hospitals, except those of the Control Department, are to be under their orders. The sick from all corps in the field—household troops, militia, yeomanry, and volunteers included—will be received into these hospitals. Each officer designated for the charge of a field hospital will draw on the Controller for the equipment and transport, and on the Apothecary of the Forces for the medical stores. These indents are to be countersigned by the principal medical officer of the division. One regimental medical officer is to accompany each regiment of cavalry, battalion or infantry, and battery of artillery, and he will take with him a Medical Field Companion, to be carried by an hospital orderly belonging to the corps, except in the case of the artillery, in which it will be carried in the store cart. Each corps will take a field stretcher, to be carried in the baggage waggon. The principal medical officer of the division will indent on the Controller for twenty ambulance waggons for the general service of the division. These will be told off to various services as he may direct. The men treated in the field hospitals will be on field rations, for which the regulated stoppage will be charged. Such of them as receive medical comforts will be subject to the additional stoppage for each day on which these are issued.

**Strange Case under the Lunacy Act.**—An important investigation under the Lunacy Act was held in the Sheriffs' Court, Dumfries, yesterday. Mr. Wilson, a gentleman from the Isle of Man, alleged to have been kidnapped into the Crichton Lunatic Asylum, Dumfries, presented a petition under the 92nd section of the act for his liberation. His wife opposed the application. Three medical certificates as to his sanity and four as to insanity were read, together with a statement on the part of his wife as to his condition before he was placed under restraint. The sheriff held that the petitioner under the section could not be the lunatic, and, accordingly, dismissed the petition.

## Citrate of Caffein in Neuralgia.

DR. G. W. ARNETT, of Bossier Parish, Louisiana, reports a number of cases in which he has had great success in the treatment of neuralgia by the use of citrate of caffein and sulphate of morphia; also in nervous headache, hysteria, and other similar diseases. His prescription varies in amount to suit the case, the average being—

Sulph. morphia. gr. ss.;  
Caffein, grs. iij.;  
Citric Acid, gr. iij.

to be given in some warm coffee, or, what is better, in a decoction of race ginger. The caffein and citric acid will, in the majority of cases, relieve nervous irritation without the addition of the morphia, which is a desideratum when the bowels are constipated. It acts powerfully on the skin, equalises the circulation, and thereby removes local congestion.—*Georgia Med. Compan.*

## NOTICES TO CORRESPONDENTS.

## NEW READING CASE.

In consequence of the postal restrictions as to stitching the Journal, improved reading cases with twenty-six strings to hold one volume can now be obtained through any bookseller in town or country, price 2s. 6d. The advantages to subscribers are, that each number when received by post has but to be slipped into the cord, no stitching or planning being required. The Journal is kept flat for reading, and each volume complete for reference. The same portfolio can be used for successive volumes where desired.

## RECENT NUMBERS OUT OF PRINT.

Full price will be given for THE MEDICAL PRESS AND CIRCULAR of November 23, 1870, and February 1, 1871, on receipt of same with name and address of sender, at the London offices of this paper, 20 King William street, Strand.

**SNAKE BITES AND ANTIDOTES.**—L. D. K. writing upon this subject states that, there is an absolute antidote for the bite of the Cobra and other reptiles. He says:—

"In the island of St. Lucia, which abounds with snakes of the most dangerous kind, is to be found a small plant, in appearance like the sorrel; the leaf is exceedingly bitter to the taste. When used as an antidote for the bite of a snake a small quantity of the juice of the leaves diluted with water is sufficient; it at once diffuses itself through the blood, and as I was informed by a woman who had been severely bitten, the sensation it causes is quite indescribable, but the cure is certain. A few of the natives are acquainted with the virtues of this plant, and guard the secret most jealously, as they get large fees from their patients. A gentleman informed me that with great difficulty he obtained the secret from an old native, who bound him to secrecy, and made him pay £5. The first opportunity he had of trying it was on the occasion of a picnic. His daughter and only child, feeling fatigued, lay down under a tree; her father amused himself by looking for this plant; when he returned to his daughter with some of it in his hand he was horrified to find a large snake of the most venomous kind lying asleep close to her ear. He cautiously approached it, seized it round the throat, chewed a few leaves and put them into its mouth; in three minutes the snake was dead. I discovered the leaf by watching a sheep which had been bitten in the side; it immediately went to a spot where the antidote grew, and ate a small quantity of it. There is abundance of it growing on Mount Fortunate."

**PERVERSION AND PUFFING.**—A Correspondent in Leicester forwards us the accompanying circular letter, which he states is being most extensively circulated in the neighbourhood. It appears that both the individuals named, possess legal qualifications. The sudden perversion of Dr. Emmerson on the retirement of Mr. Elliot, being singularly suggestive, as within twelve months of his introduction to the local profession as a genuine allopath, we find him succeeding to the Homoeopathic practice of Mr. Elliot, and handled by him over to the kind considerations of his lamb-like patients in the language of this previous puff, which we give *verbatim*, further comment being unnecessary:—

"DEAR SIR,—I am compelled by the state of my health to relinquish my Medical Practice in Leicester, and, having made a beneficial agreement with Dr. Emmerson, to succeed me in the Practice, I have great pleasure in introducing him.

"Dr. Emmerson is fully qualified, as a Doctor of Medicine, Member of the College of Surgeons, and holding four Diplomas in Medicine, Surgery, and Midwifery, from University and College, to practice in all branches of the Profession. Having also seen much of Hospital and General Practice for nearly Thirty Years, I believe him to be in every way fitted for the duties of a Family Physician.

"In leaving you in such safe Professional hands, I have somewhat less to feel in parting with those from whom I have received so much confidence and kindness during the past Eleven Years.

"As I shall for some time to come have an interest in the successful conduct of the Practice, I shall still have opportunities of hearing of my old friends.

"Believe me, Yours sincerely, HENRY ELLIOT.

"Leicester, August, 1871."

THE STUDENTS' NUMBER.—The latest arrangements at the various Medical Schools, and Advertisements cannot be received after Saturday next.

DR. BAGOT.—Write to Medical Department of the Privy Council, Richmond terrace, Whitehall.

DR. SEDGWICK S. COWPER writes stating that he has found "the vegetable-mineral oil, known in Australia as "Kerosene," procurable at about half-a-crown a gallon, wonderfully curative in the treatment of ulcerated and cancerous wounds.

MR. COLLETTET.—The review of your new "Chemical Tables for Students" has been in type some three weeks; pressure of matter having kept it and several other reviews from appearing.

MR. J. BALFOUR BROWN.—Probably the last week in September.

DR. LANE.—The copies were sent, and must have miscarried.

THE GAINSBOROUGH OFFICE OF HEALTH, Dr. Mackinder, has issued a very important report and recommendation as to the disposal of Sewage, together with analytical tests of nineteen samples of water obtained by him. The report has more than local interest, and we regret our space forbids a longer notice.

## BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A System of Medicine. Edited by J. Russell Reynolds, M.D., F.R.S. Vol. III. London: Macmillan and Co.

On the Relative Powers of Various Substances in Preventing the Generation of Animalculæ. By John Dougall, M.D. London: J. and A. Churchill.

Phrenology: how to use it in analysing Character. By Nicholas Morgan. London: Longmans, Green, and Co.

Report of the British National Society for Aid to the Wounded during the Franco-German War.

Good Health. Nature. Indian Medical Gazette. Boston Medical Journal. Lyon Médical. Australian Medical Gazette.

## VACANCIES.

Middlesex Hospital. Assistant-Surgeon. Election October 3rd. Physician's Assistant. Board and residence free.

West London Hospital. House Surgeon. Election September 14th. Queen's College, Birmingham. Medical Tutor. Stipend £10, with residence.

Workshop Dispensary. Resident Surgeon. Salary £100 per annum. Stockport Infirmary. House Surgeon. Salary £100, with board and residence.

Bethnal Green, Queen Adelaide's Dispensary. Salary £100, with residence.

Swansea Union. Western District. Medical Officer. Salary and fees, £01.

Gainsborough Dispensary. House Surgeon. Salary £100, with residence.

Dover Hospital. House Surgeon. Salary commencing at £80. (See Advertisement.)

Bristol. Medical officer to the Bristol police.

Narberth Union, Penbrokeshire. Medical officer for District No. 3.

Reeth Union. Medical officer for the Maker District.

Battle Union, Sussex. Medical officers for the Mountfield and Brightling Districts.

Liverpool. District Medical officer.

York Union. Medical officer for District No. 4.

## APPOINTMENTS.

JEFFERISS, W. R. S., M.B., C.M., L.R.C.P.E., L.R.C.S.E., Resident Surgeon and Physician to the Landore Siemens-Steel Company's New Works.

SILVER, ALEXANDER, M.D. Aberdeen, M.R.C.P. Lond., a Physician to Charing-cross Hospital, vice Henry Hyde Salter, M.D., F.R.C.P., F.R.S., deceased.

ARMY MEDICAL DEPARTMENT.—The following were Gazetted on Friday last:—

Surgeon A. D. Gulland, M.D., from 6th Foot, to be Staff Surgeon, vice E. F. O'Leary, appointed to the 6th Foot.

Assistant Surgeon R. Lewer, from Royal Artillery to be Staff Surgeon, vice F. T. Abbott, deceased.

Staff Assistant Surgeon A. Neill, from half-pay, to be Staff Assistant Surgeon, vice W. Jackson, M.D., appointed to Royal Artillery.

Assistant Surgeon J. D. Gunnar, from 1st Foot, to be Staff Assistant Surgeon, vice H. Comerford, M.D., appointed to 1st Foot.

Staff Assistant Surgeon C. Backhouse has been permitted to resign his commission.

## Births.

THOMPSON.—On September 3rd, the wife of Dr. Thompson, of 70 Oakley square, Camden Town, of a daughter.

## Marriages.

DODSWORTH—DANIELL.—On the 7th inst., at Christ Church, Chiswick, F. C. Dodsworth, of Turnham Green, L.R.C.P. Lond., to Fanny, daughter of the late Neville Daniell, Esq.

WIMBLE—POCOCK.—On the 7th inst., at St. John's Brixton, Frederick John, eldest son of F. Wimble, Esq., surgeon, of East Malling, Kent, to Annie Florence, eldest daughter of William Pocock, M.D., of Brixton.

## Deaths.

HUNTER.—On the 6th inst., at Sandhurst, Berks, Christopher Hunter, M.D., in his 90th year.

SHEPPARD.—On the 4th inst., Margaret Edith, only daughter of E. Sheppard, M.D., of Belsize square, N.E.

Every article of mess traps is now furnished by the Admiralty gratis. The same with your cabin furniture ; every necessary article except bedding is supplied from the dock-yards. An officer on joining his ship has, therefore, nothing more to pay than his mess subscription monthly. This varies in ships according to the station they are on, from 2*l.* 10*s.* to 3*l.* 10*s.* per month. This subscription does not include anything for wine or liquors of any kind. Whatever amount of these you may consume will be paid for by you separately, at the end of each month or quarter. But as all wines are permitted, by sanction of the Admiralty, to be shipped free of duty, you drink them so much cheaper on board than you could the same qualities of wine on shore. The monthly subscription, of say 3*l.* with the Government allowance of 11*l.* 3*s.* 8*d.* per annum to each member in lieu of provisions, is generally found sufficient to meet all ordinary expenses of messing.

It is the custom in all wardroom messes to have an extra dinner on two days of the week—generally Monday and Thursday. The days so selected are styled "field-days." It is on these days that guests are invited to dine by the mess. The guests thus invited are called public guests, and such invitations entail no extra subscription from any one, except for the extra wine consumed. It is usual to invite the captain, and other superior officer that may be on board, once a week ; the other public guests are so many of the junior officers of the ship ; and, if in port, officers of the sister service, and other public functionaries. The captain, or admiral, if there be one on board, usually has two or three wardroom, and two or three gunroom officers, to dine with him on every other day of the week than that on which he dines in the wardroom. Any member of the wardroom mess inviting a private friend to dine with him on board, pays usually from 2*s.* 6*d.* to 3*s.* 6*d.* (according to the rule of the mess) for his friend's dinner, in addition to any extra expense for wine.

The foregoing are the whole of the ordinary and extraordinary expenses of messing in the wardrooms of Her Majesty's ships, and which should not, with drinking a reasonable quantity of wine, beer, &c., exceed fifty guineas per annum.

Officers in the Navy, wherever they may be serving, can remit, by the paymaster of the ship, without any expense, any portion, or the whole, of their pay that may be due to them on the last day of each quarter.

SERVANTS.

Assistant-surgeons are allowed only half a servant each ; or in other words, a servant between two of them.

These servants are entered on the ship's books with the rating of officer's servant. Their pay from the Admiralty is about 17*l.* per annum and their provisions ; and where they are well conducted, attentive lads, it is usual for each of their masters to give them 10*s.* a month, which makes their pay up to about 29*l.* per annum.

The pay of naval medical officers has hitherto been the same as for their military brethren.

EXTRA PAY AND ALLOWANCES.

The following extra pay and allowances are paid to naval medical officers under the conditions stated below :—

|   | At Home. | Abroad. |
|---|----------|---------|
| Inspectors-General in lieu of provisions for their servants, and of the ordinary allowances for provisions for themselves | £54      | £130    |
| Deputy Inspectors-Generals, Staff-Surgeons, and Surgeons, do. do. ..  | £35      | £112    |
| Assistant-Surgeons do. do. ...  | £30      | £108    |

Staff-surgeons, when serving in flag-ships on foreign stations, are allowed extra pay of five shillings per diem.

Staff-surgeons, surgeons, and assistant surgeons, when serving in ships in which there is no accommodation for residing on board, as in drill ships for the Royal Naval Reserve, are

allowed 50*l.* per annum for lodgings, and one and sixpence per diem in addition in lieu of ship's rations.

Whenever medical officers are employed on extra duty, they are allowed such extra pay as it may appear to the Lords Commissioners of the Admiralty the nature of the service merits.

Medical officers, when travelling on the public service, are allowed on the home stations—in addition to all expenses of first class fare by rail or otherwise—for subsistence :—

|   | Special Service occupying 12 hours. | Ditto for every 24 hours. |
|---|-------------------------------------|---------------------------|
| Inspector-General and Deputy Inspectors-General | £0 12 0                             | £1 0 0                    |
| Staff-Surgeons and Surgeons                     | 0 7 6                               | 0 10 0                    |
| Assistant-Surgeons                              | 0 6 0                               | 0 7 6                     |

PENSIONS OF MEDICAL OFFICERS.

Besides the half-pay awarded to medical officers, there are three good-service pensions of 10*s.* each per diem awarded to the three inspectors-general who have completed the longest and most meritorious services.

There is also one Greenwich Hospital pension of 80*l.* per annum awarded to a deputy inspector-general.

There are fourteen other Greenwich Hospital pensions of 50*l.* each per annum, awarded to those fourteen deputy inspectors-general, staff-surgeons, and surgeons who are considered by the Admiralty to be most deserving of them

PROMOTIONS.

An assistant-surgeon having served three years may be examined as to his qualifications for promotion to the rank of surgeon. If he be serving abroad he may, if he wish it, be examined provisionally by an inspector or deputy inspector-general and three surgeons ; and as soon after his arrival in England as may be convenient for him to present himself at Somerset House for his regular and final examination. To enable assistant-surgeons to pass this examination satisfactorily they are granted, on application, two months' leave of absence to prepare themselves for it. The use of passing the provisional examination abroad is, that the assistant-surgeon, having served five years, is then eligible for promotion into any vacancy that may occur, as acting surgeon.

If the vacancy occurring shall have been caused by the death of an officer of superior rank, this promotion as acting-surgeon will be confirmed as surgeon on passing the regular examination at Somerset House. If the vacancy has occurred from any other cause than that of death, the assistant-surgeon appointed to fill it, whether he may have passed only provisionally or finally, will be appointed only as acting-surgeon until the pleasure of the Admiralty be known, who may either confirm him in it, or supersede him by the appointment of a surgeon from half-pay.

Surgeons are promoted to the rank of staff-surgeons on twenty years' service, provided that ten years have been completed since passing for the rank of surgeon.

By an Admiralty regulation, dated the 12th of July, 1867, promotion to staff-surgeon is to be open to officers for distinguished or special services, although they may not have completed twenty years' service.

An officer may be promoted to the rank of inspector-general on the completion of thirteen years' service from the date of his entry into the Royal Navy.

PRIZE MONEY.

Medical officers share in the proceeds of all prizes captured from the enemy, of captures and seizures under the several Acts of Parliament passed relating to the revenues of customs, and to trade and navigation, for the abolition of the slave trade, for the capture and destruction of pirates and piratical vessels ; and of the rewards conferred for the same ; as also in the awards of all salvage granted to the crews of Her Majesty's ships and vessels of war, with other officers of corresponding ranks.

### POOR-LAW MEDICAL SERVICE.

A young qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps obtain a Poor-law appointment, though he should scarcely expect to obtain a livelihood from this inadequately remunerated employment.

#### ENGLISH POOR-LAW MEDICAL SERVICE.

Prior to the passing of the Metropolitan Poor Act of 1867, the English Poor-law Medical Service may be said to have been in the hands of the Guardians, supervised by the Poor-law Board. Each parish in England and Wales had its guardians of the poor, and these parishes were grouped together to form unions. The unions were divided into districts for medical relief. Union medical officers, therefore, have the care of a district, or sometimes the care of the workhouse of the union—sometimes of both. The officer was elected by the guardians, and the appointment approved by the Board. He was required to have both a medical and a surgical qualification. In some instances these were specified, but almost always the London College of Surgeons and Apothecaries' Hall were the two most favoured diplomas. For this reason London students will still continue to take these qualifications, whatever else they may add to them. But the L.R.C.P. Lond. is now recognised as a full qualification, both medical and surgical. The salaries of Poor-law appointments are very low. They are, however, sought after by young men as a means of getting into practice, and are often almost obligatory in the country to prevent fresh opposition being introduced. The Metropolitan Poor-law Act, 1867, assimilates the Poor-law, so far as London is concerned, to that of Ireland, and the Poor-law Board is, by an Act of last session, merged in the new local Government Board. It establishes in London asylums and dispensaries, and distributes the cost of supporting them over the metropolis. The Acts have not yet come into full operation.

### THE IRISH POOR-LAW SERVICE.

THE newly-qualified Medical Practitioner, who may elect to try his luck in the Irish provinces, sets his hopes, in the great majority of instances, upon obtaining one or more Poor-law Medical appointments in some district where there is hope of private practice. There are 163 workhouses and 793 Dispensary Medical Officers, besides apothecaries. The number of vacancies that occur annually average 100. The average salary in this service is £90; and when it is taken into consideration that, in the vast majority of rural districts, it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a very large margin left from the public emoluments. The Medical Officer will also have the refusal of the Registrarship of Births, Marriages, and Deaths, which office in country districts seldom yields more than £10 a year, and often not half that amount. Despite the miserable salary and the very many discomforts of a dispensary life, these appointments are generally eagerly sought for—firstly, because they afford the new comer a certain though hardly-earned salary to supplement his private earnings; and, secondly, because, if not secured by the new comer, they would of necessity bring a competitor for practice into the field, and inasmuch as private income is of far greater import than public earnings, country Medical practitioners are obliged to undertake the public duty in order to save to themselves the monopoly of their private emoluments.

#### APPOINTMENT.

The qualifications required by the Poor-law Commissioners are a licence in Surgery or a diploma in Medicine, and a diploma in Midwifery; the candidate must also be twenty-three years of age.

The appointment lies with the Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter into the election of Poor-law Medical Officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required. And whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential. And, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away. We may here observe, also, that in very many instances the appointment is virtually made before the advertisement appears for a Medical Officer, in which case also candidates are put to unnecessary trouble and expense under false pretences.

#### CONTROL.

Each district is under the direct control of a committee composed of the neighbouring landholders, the appointment of medical and other officers are made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Poor-law Commissioners, who have the power either of interposing their veto on any appointment, or even of expelling an officer by a "sealed order," without trial or accusation, and without the resource of appeal or investigation. This salary is paid by the Board of Guardians, and no increase or decrease can be made in the amount without their assent and that of the Commissioners. Under the late Sanitary Act the committee may recompense the Medical Officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The number of unions in Ireland is 163, to each of which is attached a Medical Officer, who is appointed and controlled by the Board of Guardians in the same manner as the Dispensary Surgeon is by his committee. The salary is usually better than that of the Dispensary Doctor, and the duties of a more easy and satisfactory description, inasmuch as the duty is confined to daily attendance at the Workhouse Hospital, and no night visits out of doors or any long journeys across the country are involved.

#### DUTIES.

The duty of the Dispensary Doctor is twofold. He is to attend his Dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have, perhaps, to attend two days at each. He has also to visit at any hour of the day or night a sick person, for whose relief a visiting ticket has been issued by a member of the committee or by the relieving officer, and to continue his attendance as often as may be necessary until a termination of the case. Moreover, he has a great many registry books to keep, and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependent on the goodwill of the members of his committee. If the medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour of the paper on which they are printed, humourously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee-men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—

Aye! even the committeeman's own brother or daughter. The law unfortunately leaves the Poor-law Medical Officer no protection, and no alternative is open to him but to resign or endure insults and annoyances of the most galling description.

By a recent Act of Parliament Poor-law Medical Officers may now receive a pension of *one-sixtieth of their salary for each year of service* on being incapacitated from illness or old age. This grant is strictly at the discretion of the guardians, nevertheless it has been given in most cases in which physical incapacity has been clearly proved. It is, however, at best a miserable resource, and can by no means be calculated upon as a provision for old age.

#### SURGEONCIES IN THE MERCANTILE MARINE SERVICE.

The appointment of surgeon in sea-going vessels is much sought after by young surgeons who are desirous of seeing a little more of the world than school, college, or home, have shown them; but the office is seldom held for more than a few years, or regarded as a permanent provision for life. These appointments are almost uniformly in the gift of directors and secretaries of companies, and of the owners themselves, with whom, as may be believed, personal influences are a better recommendation than any professional qualification.

The Peninsular and Oriental Service heads the list in respect of its eligibility, and admission to it is a matter generally quite outside the range of the unfriended candidate.

The appointment is made by the directors, and the surgeon is bound for three years' service. He is placed always at first on some of the lines at the other side of the Isthmus of Suez, and is drafted into the "home" service between England and Alexandria, as vacancies occur. The pay is at first twelve guineas per month, which is afterwards increased, and he is permitted to receive such fees as may be offered for attendance on passengers, whom, however, he is bound to attend without charge, if required to do so. Occasionally large fees are paid by grateful patients; but usually the income from this source is not large, and less in the home service than elsewhere.

The surgeon can resign on giving a month's notice when on leave—*i.e.*, when his ship is laid up.

The Cunard and other American mail lines select their surgeons through the interest of owners and managers. The American ships are bound to carry American surgeons, and the English ships English medical officers. The pay varies from ten guineas per month upwards, and the arrangement may be terminated by the surgeon at any time that the ship is laid up. If, however, he has signed special articles, he will of course, be bound by them.

The West India Mail Service admits candidates only between the ages of twenty-two and forty. A regular curriculum similar to that required by the licensing bodies, is necessary, and a special examination in climateric disease is administered to the candidate.

The following is the scale of pay:—At entrance £100 a-year, Senior Surgeon, £120, amounting with all fees generally to about £200. When the ships are engaged on transport service the pay is doubled. Surgeons in the service have a private cabin and a boy to assist in dispensing. They mess in the saloon, and are found in every requirement free of charge. A pint of wine is included in each day's rations, or in lieu of it a payment of 1s. 3d. At entry surgeons are requested to join vessels in the West Indies or Brazils relieving surgeons longest out, and being themselves relieved in turn. The fees in this service are much better than in the P. & O. The emigration Commissioners are now reducing their staff, and making no appointments to vacancies as they occur. Many of the trading ships which carry emigrants to New Zealand and Australia

take surgeons only on their outward voyage, and call at China for silks and other freight on their way home. Surgeons to these vessels are paid only £35, and finding it impossible to obtain a passage home again are compelled to settle in the colonies which are accordingly overstocked.

*European Communities.*—There is a growing demand for surgeons for small European colonies, and several desirable appointments have thus been recently made. A number of colonists feeling the want of efficient medical advice subscribe an annual guarantee salary of say £600. These appointments have been made through the agency of Mr. Langley, of Lincoln's Inn Fields; as, however, they are few and somewhat lucrative, the communities are entitled to expect a high degree of education and intelligence in their medical attendant.

#### THE ASSISTANT—HIS DUTIES AND OBLIGATIONS.

ALMOST every provincial general medical practitioner in England has his qualified or unqualified assistant, and the probationary service of the private practitioner himself is thus very frequently in this capacity. As may be presumed, the duties of the office are very various, and the relations between principal and assistant very complex, so much so as to demand a special volume for themselves: We have availed ourselves of Mr. Langley's permission to extract from the pages of "Via Medica" certain passages which are essential to the student.

#### THE PUPIL ASSISTANT.

The pupil-assistant is usually a young gentleman who enters into the service of his employer to learn pharmacy and the manipulation of dispensing without present remuneration, or who gives his services in return for board and lodging with a nominal salary. If there be any articles of apprenticeship the relations between the junior and his employer are those which exist under apprenticeships generally, subject to the terms and conditions stated in the indenture itself.

The *unqualified* assistant (without diploma) capable of visiting patients, diagnosing disease, prescribing, dispensing, attending midwifery, drawing teeth, bleeding, cupping, applying the tourniquet, opening an abscess, dressing a wound, &c., &c., is generally a young man who has passed through his pupilage or apprenticeship, seen something of country practice, spent a year or two at the hospital and medical school, and who, having limited means, desires to recruit his resources.

Qualified men (with single or double diploma) are generally required for *out-door appointments*, in which the assistant does not reside with his principal. Indeed, it may be remarked that the tendency generally seems to be towards the employment of gentlemen with diplomata in preference to those without, because the employer is rendered more free to absent himself, occasionally, if he can leave his practice in the hands of a substitute who can legally take charge of his parochial appointments, or, in case of accidents, give evidence before the coroner.

Constant applications are made by gentlemen from Ireland, who, having degrees in arts, honours in medicine, and high testimonials as to personal character, do not understand why they cannot at once obtain employment as assistants in England, in town or country practice. If they are asked what they know of private dispensing, they reply that they are competent to undertake anything of that kind because they have done it at the hospital. They cannot understand that aptitude in private dispensing—apothecary's work—is essential in English practice as it is at present conducted, and they are unwilling to believe that a mere power of manipulation is an absolute requisite if they would obtain employment here.

It is almost useless for gentlemen from Ireland and Scotland seeking employment unless they can produce testimonials (those of college teachers will not suffice) from persons who know the applicants in private life, and who can give direct evidence as to their *private* character and personal habits.

#### THE OUT-DOOR ASSISTANT.
